1 Introduction ..... 1
1.1 Main tasks ..... 1
1.2 Participants ..... 2
1.3 Management framework for salmon in the North Atlantic ..... 4
1.4 Management objectives ..... 5
1.5 Reference points and application of precaution ..... 5
2 Atlantic salmon in the North Atlantic area ..... 7
2.1 Catches of North Atlantic salmon ..... 7
2.1.1 Nominal catches of salmon ..... 7
2.1.2 Catch and release. ..... 9
2.1.3 Unreported catches ..... 9
2.2 Farming and sea ranching of Atlantic salmon ..... 10
2.2.1 Production of farmed Atlantic salmon ..... 10
2.2.2 Harvest of ranched Atlantic salmon ..... 10
2.3 NASCO has asked ICES to report on significant, new or emerging threats to, or opportunities for, salmon conservation and management ..... 11
2.3.1 Impacts of COVID-19 ..... 11
2.3.2 Threats ..... 11
2.3.2.1 ISA noted in farmed salmon in sea-pens in Iceland for the first time ..... 11
2.3.2.2 Update on Red Skin Disease ..... 12
2.3.2.3 Update on sea lice investigations in Norway ..... 12
2.3.2.4 Gyrodactylus in Norway ..... 13
2.3.2.5 Offshore Fish Farming in Norway ..... 13
2.3.3 Opportunities ..... 13
2.3.3.1 Estimating homewater catches and returns in France ..... 13
2.3.3.2 Effect of Catch-and-Release and temperature on reproductive success on a Quebec river ..... 14
2.4 Provide information on causes of variability in return rates between rivers within regions in the North Atlantic ..... 14
2.4.1 Data Considerations ..... 15
2.4.2 Genetics and equilibrium population considerations ..... 16
2.4.3 Regional variations and differences in return rates ..... 16
2.4.4 Factors contributing to variation in return rates ..... 17
2.4.4.1 Carryover effects from freshwater ..... 18
2.4.4.2 Carryover effects from estuarine and nearshore areas ..... 18
2.4.4.3 Geographic scale effects ..... 19
2.4.5 Effects at North Atlantic scale ..... 19
2.4.5.1 Bottom up effects (prey) ..... 19
2.4.5.2 Top-down effects (predation) ..... 20
2.4.6 Genetic perturbations associated with domestication ..... 20
2.4.7 Conclusion ..... 21
2.5 Provide a summary of the most recent findings of ongoing research projects investigating the marine phase of Atlantic salmon (e.g. SeaSalar, SeaMonitor, SAMARCH, satellite tagging at Greenland ..... 21
2.5.1 Atlantic Salmon Federation's Acoustic Tracking ..... 21
2.5.2 Environmental Studies Research Fund ..... 22
2.5.3 Atlantic salmon at sea - factors affecting their growth and survival (SeaSalar) ..... 22
2.5.4 SAlmonid MAnagement Round the CHannel (SAMARCH) ..... 23
2.5.5 Pop-off satellite tagging at Greenland ..... 24
2.5.6 SeaMonitor ..... 25
2.5.7 SMOLTRACK ..... 26
2.6 Provide a summary of the current state of knowledge on freshwater and marine predation by cormorants and impact on stocks ..... 26
2.7 Data Call for NASCO requested information used by the Working Group ..... 28
2.7.1 Process for collating catch data ..... 28
2.7.2 Review of the 2023 Data Call ..... 29
2.8 Progress on developing the Atlantic salmon Benchmark ..... 29
2.9 Reports from ICES expert group and other investigations relevant to North Atlantic salmon ..... 30
2.9.1 WGDIAD ..... 30
2.10 NASCO has asked ICES to provide a compilation of tag releases by country in 2021 and 2022 ..... 31
3 Northeast Atlantic Commission area ..... 95
3.1 NASCO has requested ICES to describe the key events of the 2021 and 2022 fisheries ..... 95
3.1.1 Fishing at Faroe Islands ..... 95
3.1.2 Key events in NEAC homewater fisheries ..... 95
3.1.3 Gear and effort ..... 95
3.1.4 Catches ..... 96
3.1.5 Catch per unit of effort (CPUE) ..... 97
3.1.6 Age composition of catches ..... 98
3.1.7 Farmed and ranched salmon in catches ..... 98
3.1.8 National origin of catches ..... 99
3.1.8.1 Catches of Russian salmon in northern Norway ..... 99
3.1.9 Exploitation indices of NEAC stocks ..... 99
3.2 Management objectives and reference points ..... 100
3.2.1 NEAC conservation limits ..... 100
3.2.2 Progress with setting river-specific conservation limits ..... 101
3.2.2.1 France ..... 101
3.2.2.2 Finland/Norway ..... 101
3.3 Status of stocks ..... 101
3.3.1 The NEAC PFA run-reconstruction model ..... 101
3.3.2 Changes to the national input data for the NEAC PFA run-reconstruction model ..... 102
3.3.3 Changes to the NEAC PFA run-reconstruction model ..... 103
3.3.4 Description of national stocks and NEAC stock complexes as derived from the NEAC run-reconstruction model ..... 103
3.3.4.1 Individual country stocks ..... 104
3.3.5 Compliance with river-specific conservation limits ..... 105
3.3.6 Return rates ..... 106
3.4 Advice on the risks of salmon bycatch occurring in pelagic and coastal fisheries and effectiveness and adequacy of current bycatch monitoring programmes ..... 107
North American Commission ..... 222
4.1 NASCO has requested ICES to describe the key events of the 2021 and 2022 fisheries ..... 222
4.1.1 Key events of the 2021 and 2022 fisheries ..... 222
4.1.2 Gear and effort ..... 222

## i Executive summary

WGNAS met to consider the status of and threats to Atlantic salmon in the North Atlantic Salmon Conservation Organization (NASCO) commission areas: West Greenland (WGC), North American (NAC), and Northeast Atlantic (NEAC). Many updates are provided for 2021 and 2022 as WGNAS was not able to address all terms of reference (ToRs) in 2022. Information on the catch and exploitation, including salmon caught and released, and nominal harvest, as well as tagged and marked fish releases are provided by country and jurisdiction. Emerging threats are presented, including the first report of Infectious Salmon Anaemia (ISA) in Iceland, red skin disease in Europe, and Norway is evaluating new offshore farming sites. New scientific advancements reported on include non-lethal Gyrodactylus treatment, homewater return rate estimation methods, and genetic tools to understand the reproductive success of salmon that have been caught and released. ICES did not conduct a full assessment for salmon in NEAC because the Framework of Indicators (FWI) did not indicate that the forecast estimates of abundance for the four NEAC stock complexes had been underestimated.

WGNAS was asked to provide information on three key issues in 2023, namely:

1. the causes of variability in return rates between rivers within regions of the North Atlantic, concluding that factors at river-specific, regional and oceanic scales interact to affect marine survival rates and maturation schedules, and it is unlikely that a single factor alone accounts for temporal variations and the decline of wild salmon in the North Atlantic;
2. the current state of knowledge on freshwater and marine predation by cormorants, concluding that cormorants can have substantial impacts on salmon abundance in areas where cormorant populations have increased or declines in other cormorant prey abundance have occurred, an issue of special concern where salmon populations are already threatened or endangered; and,
3. an evaluation of the risk of salmon bycatch occurring in pelagic and coastal fisheries, and effectiveness and adequacy of current bycatch monitoring programmes, concluding that ICES ability to evaluate the risk of bycatch is limited because few pelagic fisheries are screened for bycatch and screening covers small proportions of catch. To advance our capacity to evaluate such risks, a series of data deficiencies, monitoring needs and research requirements are identified.

Looking forward, a Bayesian life cycle assessment model and data inputs were discussed in connection with the 2023 benchmark.

## ii Expert group information

| Expert group name | Working Group on North Atlantic Salmon (WGNAS) |
| :--- | :--- |
| Expert group cycle | Annual |
| Year cycle started | 2023 |
| Reporting year in cycle | $1 / 1$ |
| Chairs | Martha Robertson (Canada) |
| Meeting venues and dates | $14-15$ February 2023, Online, 27 |

## 1 Introduction

### 1.1 Main tasks

On 10 March 2023, ICES resolved in C. Res. 2022/2/FRSG17 that the Working Group on North Atlantic Salmon (WGNAS) would meet in two parts:
4. from 14-15 February 2023 to address ToR 2.4 via online web conference, chaired by Cindy Breau (CA)
5. from 27 March-6 April 2023 at the Black Diamond and in ICES HQ in Copenhagen, Denmark, during hybrid meetings chaired by Alan Walker (UK) and Martha Robertson (CA).

The working group met according to this schedule, to address questions posed to ICES by the North Atlantic Salmon Conservation Organization (NASCO).

The terms of reference were met.
The sections of the report which provide the answers to the questions posed by NASCO are identified below:

| Question posed by NASCO |  | Report section |
| :---: | :---: | :---: |
| No. |  |  |
| 1 | With respect to Atlantic salmon in the North Atlantic area: | Section 2 |
| 1.1 | provide an overview of salmon catches and landings by country, including unreported catches and catch and release, and production of farmed and ranched Atlantic salmon in 2021 and 2022;1 | 2.1, 2.2 and Annex 4 |
| 1.2 | report on significant new or emerging threats to, or opportunities for, salmon conservation and management; ${ }^{2}$ | 2.3 |
| 1.3 | provide information on causes of variability in return rates between rivers within regions in the North Atlantic | 2.4 |
| 1.4 | provide a summary of the most recent findings of ongoing research projects investigating the marine phase of Atlantic salmon (e.g. SeaSalar, SeaMonitor, SAMARCH, satellite tagging at Greenland); | 2.5 |
| 1.5 | provide a summary of the current state of knowledge on freshwater and marine predation by cormorants and impact on stocks | 2.6 |
| 1.6 | provide a compilation of tag releases by country in 2021 and 2022; | 2.10 |
| 1.7 | identify relevant data deficiencies, monitoring needs and research requirements; | Annex 7 |
| 2 | With respect to Atlantic salmon in the Northeast Atlantic Commission area: | Section 3 |

[^1]| Question posed by NASCO |  | Report section |
| :---: | :---: | :---: |
|  | describe the key events of the 2021 and 2022 fisheries; ${ }^{3}$ | 3.1 |
| 2.2 | review and report on the development of age-specific stock conservation limits, including updating the time-series of the number of river stocks with established CLs by jurisdiction; | 3.2 |
| 2.3 | describe the status of the stocks, including updating the time-series of trends in the number of river stocks meeting CLs by jurisdiction. | 3.3 |
| 2.4 | advise on the risks of salmon bycatch occurring in pelagic and coastal fisheries, and report on effectiveness and adequacy of current bycatch monitoring programs | 3.4 |
| 3 | With respect to Atlantic salmon in the North American Commission area: | Section 4 |
| 3.1 | describe the key events of the 2021 and 2022 fisheries (including the fishery at Saint Pierre and Miquelon); ${ }^{3}$ | 4.1 |
| 3.2 | update age-specific stock conservation limits based on new information as available, including updating the time-series of the number of river stocks with established CLs by jurisdiction; and | 4.2 |
| 3.3 | describe the status of the stocks, including updating the time-series of trends in the number of river stocks meeting CLs by jurisdiction. | 4.3 |
| 4 | With respect to Atlantic salmon in the West Greenland Commission area: | Section 5 |
| 4.1 | describe the key events of the 2021 and 2022 fisheries; ${ }^{3}$ and | 5.1 |
| 4.2 | describe the status of the stocks. ${ }^{4}$ | 5.3 |
| 5 | Address relevant points in the Generic ToRs for Regional and Species Working Groups for each salmon stock complex. | Section 6 |

### 1.3 Management framework for salmon in the North Atlantic

The advice generated by ICES in response to the Terms of Reference posed by the North Atlantic Salmon Conservation Organization (NASCO), is pursuant to NASCO's role in international management of salmon. NASCO was set up in 1984 by international convention (the Convention for the Conservation of Salmon in the North Atlantic Ocean), with a responsibility for the conservation, restoration, enhancement, and rational management of wild salmon in the North Atlantic. While sovereign states retain their role in the regulation of salmon fisheries for salmon originating in their own rivers, distant water salmon fisheries, such as those at Greenland and Faroes, which take salmon originating in rivers of another Party are regulated by NASCO under the terms of the Convention. NASCO now has six Parties that are signatories to the Convention, including the EU which represents its Member States.

NASCO discharges these responsibilities via three Commission areas shown below:

### 1.4 Management objectives

NASCO has identified the primary management objective of that organization as:
"To contribute through consultation and cooperation to the conservation, restoration, enhancement and rational management of salmon stocks taking into account the best scientific advice available".

NASCO further stated that "the Agreement on the Adoption of a Precautionary Approach states that an objective for the management of salmon fisheries is to provide the diversity and abundance of salmon stocks" and NASCO's Standing Committee on the Precautionary Approach interpreted this as being "to maintain both the productive capacity and diversity of salmon stocks" (NASCO, 1998).

NASCO's Action Plan for Application of the Precautionary Approach (NASCO, 1999) provides interpretation of how this is to be achieved, as follows:

- "Management measures should be aimed at maintaining all stocks above their conservation limits by the use of management targets".
- "Socio-economic factors could be taken into account in applying the Precautionary Approach to fisheries management issues".
- "The precautionary approach is an integrated approach that requires, inter alia, that stock rebuilding programmes (including, as appropriate, habitat improvements, stock enhancement, and fishery management actions) be developed for stocks that are below conservation limits".

### 1.5 Reference points and application of precaution

Conservation limits (CLs) for North Atlantic salmon stock complexes have been defined as the level of stock (number of spawners) that will achieve long-term average maximum sustainable yield (MSY). In many regions of North America, the CLs are calculated as the number of spawners required to fully seed the wetted area of the river. The definition of conservation in Canada varies by region and in some areas, historically, the values used were equivalent to maximizing/ optimizing freshwater production. These are used in Canada as limit reference points and they do not correspond to MSY values. In some regions of Europe, pseudo stock-recruitment observations are used to calculate a hockey-stick relationship, with the inflection point defining the CLs. In the remaining regions, the CLs are calculated as the number of spawners that will achieve long-term average MSY, as derived from the adult-to-adult stock and recruitment relationship (Ricker, 1975; ICES, 1993). NASCO has adopted the region-specific CLs (NASCO, 1998). These CLs are limit reference points ( $\mathrm{S}_{\mathrm{lim}}$ ); having populations fall below these limits should be avoided with high probability.

Atlantic salmon has characteristics of short-lived fish stocks; mature abundance is sensitive to annual recruitment because there are only a few age groups in the adult spawning stock. Incoming recruitment is often the main component of the fishable stock. For such fish stocks, the ICES MSY approach is aimed at achieving a target escapement (MSY Bescapement, the amount of biomass left to spawn). No catch should be allowed unless this escapement can be achieved. The escapement level should be set so there is a low risk of future recruitment being impaired, similar to the basis for estimating $\mathrm{B}_{\mathrm{pa}}$ in the precautionary approach. In short-lived stocks, where most of the annual surplus production is from recruitment (not growth), MSY Bescapement and $B_{p a}$ might be expected to be similar.

It should be noted that this is equivalent to the ICES precautionary target reference points $\left(\mathrm{S}_{\mathrm{pa}}\right)$. Therefore, stocks are regarded by ICES as being at full reproductive capacity only if they are
above the precautionary target reference point. This approach parallels the use of precautionary reference points used for the provision of catch advice for other fish stocks in the ICES area.

Management targets have not yet been defined for all North Atlantic salmon stocks. When these have been defined, they will play an important role in ICES advice.

For the assessment of the status of stocks and advice on management of national components and geographical groupings of the stock complexes in the NEAC area, where there are no specific management objectives:

- ICES requires that the lower bound of the confidence interval of the current estimate of spawners is above the CL for the stock to be considered at full reproductive capacity.
- When the lower bound of the confidence limit is below the CL, but the midpoint is above, then ICES considers the stock to be at risk of suffering reduced reproductive capacity.
- Finally, when the midpoint is below the CL, ICES considers the stock to be suffering reduced reproductive capacity.

For catch advice on fish exploited at West Greenland (primarily non-maturing 1SW fish from North America and non-maturing 1SW fish from Southern NEAC), ICES has adopted, a risk level of $75 \%$ of simultaneous attainment of management objectives (ICES, 2003) as part of a management plan agreed by NASCO. ICES applies the same level of risk aversion for catch advice for homewater fisheries on the North American stock complex.

NASCO has not formally agreed a management plan for the fishery at Faroes. However, the Working Group has developed a risk-based framework for providing catch advice for fish exploited in this fishery (mainly MSW fish from NEAC countries). Catch advice is currently provided at both the stock complex and country/jurisdiction levels (for NEAC stocks only) and catch options tables provide both individual probabilities and the probability of simultaneous attainment of meeting proposed management objectives for both. ICES has recommended (ICES, 2013) that management decisions should be based principally on a $95 \%$ probability of attainment of CLs in each stock complex/country individually. The simultaneous attainment probability may also be used as a guide, but managers should be aware that this will generally be quite low when large numbers of management units are used.

## 2 Atlantic salmon in the North Atlantic area

### 2.1 Catches of North Atlantic salmon

### 2.1.1 Nominal catches of salmon

This year we used R software to create the tables and figures instead of Microsoft Excel. Please be aware that there are some rounding differences between R and Excel which can cause slight variations in displayed numbers and sums. In particular, R is IEC 605599 compliant when rounding fractions, and Excel is not. For example, R will round 2.5 as " 2 " and Excel will display 2.5 with no decimal places as " 3 ". We have tried to preserve precision as best we can.

The nominal catch of a fishery is defined as the round, fresh weight of fish that are caught and retained, and reported. Total nominal catches of salmon reported by country in all fisheries for 1960-2022 are given in Table 2.1.1.1. Catch statistics in the North Atlantic also include fish-farm escapees and, in some Northeast Atlantic countries, ranched fish (see Section 2.2.2). Catch and release has become increasingly commonplace in some countries, but these fish do not appear in the nominal catches (see Section 2.1.2).

Icelandic catches have traditionally been split into two categories, wild and ranched, reflecting the fact that Iceland has been the main North Atlantic country where large-scale ranching has been undertaken with the specific intention of harvesting all returns at the release site and with no prospect of wild spawning success. The release of smolts for commercial ranching purposes ceased in Iceland in 1998, but ranching for rod fisheries in two Icelandic rivers continued into 2021 and 2022 (Table 2.1.1.1). Catches in Sweden are split between wild and ranched categories over the entire time-series. The latter fish represent adult salmon which have originated from hatchery-reared smolts, and which have been released under programmes to mitigate for hydropower development schemes. These fish are also exploited very heavily in homewaters and have no possibility of spawning naturally in the wild. While ranching does occur in some other countries (Ireland, UK (Northern Ireland), this is on a much smaller scale. Some of these operations are experimental and at others harvesting does not occur solely at the release site. The ranched component in these countries has therefore been included in the nominal catch.

Figure 2.1.1.1 shows the total reported nominal catch of salmon grouped by the following areas: 'Northern Europe' (Norway, Russia, Finland, all Iceland, Sweden and Denmark); 'Southern Europe' (Ireland, UK (Scotland), UK (England and Wales), UK (Northern Ireland), France and Spain); 'North America' (Canada, USA and St Pierre and Miquelon (France)); and 'Greenland and Faroes'.

The total nominal catches for 2021 and 2022 (provisional) were 630 and 700 t , respectively. The 2021 nominal catch was 276 t below the updated 2020 catch ( 906 t ) and below the previous fiveand ten-year means (inclusive) by 483 t and 632 t , respectively. Although, nominal catches increased in 2022, they were still below the 2020 catch by 206 t and below the previous five- and ten-year means by 223 t and 391 t , respectively. Catches in the majority of countries/jurisdictions in 2021/2022 were below the previous five- and ten-year means and several countries (Finland, Iceland, Ireland, Norway, UK (England and Wales), UK (Northern Ireland) and UK (Scotland)) recorded their lowest ever catch (period 1960-2022) in either 2021 or 2022 (Table 2.1.1.1).

Nominal catches (weight only) in homewater fisheries were split, where available, by sea age or size category (Table 2.1.1.2). The data for 2022 are provisional and, as in Table 2.1.1.1, include both wild and reared salmon and fish-farm escapees in some countries. A more detailed
breakdown, providing both numbers and weight for different sea age groups for most countries, is provided in Annex 4. Countries use different methods to partition their catches by sea age class (outlined in the footnotes to Annex 4). The composition of catches in different areas is discussed in more detail in Sections 3, 4, and 5.

ICES recognizes that mixed-stock fisheries present particular threats to stock status (ICES, 2019a). These fisheries predominantly operate in coastal areas and NASCO specifically requests that the nominal catches in homewater fisheries be partitioned according to whether the catch is taken in coastal, estuarine or riverine areas. Figure 2.1.1.2 presents these data on a country-bycountry basis. It should be noted, however, that the way in which the nominal catch is partitioned among categories varies between countries, particularly for estuarine and coastal fisheries. For example, in some countries these catches are split according to particular gear types whereas in other countries the split is based on whether fisheries operate inside or outside headlands. While it is generally easier to allocate the freshwater (riverine) component of the catch, it should also be noted that catch and release ( $C \& R$ ) is now in widespread use in many countries (Section 2.1.2) and these fish are excluded from the nominal catch. Noting these caveats, these data are considered to provide the best available indication of catch in these different fishery areas. Figure 2.1.1.2 shows that there is considerable variability of the distribution of the catch among individual countries. There have been no coastal fisheries in Iceland, Spain, or Denmark throughout the time-series. Coastal fisheries ceased in Ireland in 2007 and no fishing has occurred in coastal waters of UK (Northern Ireland) since 2012, in UK (Scotland) since 2016, or in the UK (England and Wales) since 2019 (England) and 2020 (Wales). In most countries in recent years, the majority of the catch has been taken in rivers and estuaries.

Coastal, estuarine and in-river catch data for the period 2009 to 2022 aggregated by region are presented in Figure 2.1.1.3 and the whole time-series are presented in Table 2.1.1.3.

In the Northern NEAC area, catches in coastal fisheries have declined from 306 t in 2009 to 115 t in 2021 and 153 t in 2022, and in-river catches have declined from 594 t in 2009 to 287 t in 2021 and 357 t in 2022. At the beginning of the time-series about half the catch was taken in coastal waters and half in rivers, whereas since 2008 the coastal catch represents around $30 \%-40 \%$ of the total.

In the Southern NEAC area, catches in coastal and estuarine fisheries have declined over the period. While coastal and estuarine fisheries have historically made up the largest component of the catch, coastal fisheries dropped sharply in 2007 (from 306 t in 2006 to 71 t in 2007) and remained at lower levels to 2018; there have been no coastal catches since 2019. Estuarine fisheries have also declined, from 72 t in 2007 to 20 t in 2021 and 14 t in 2022. The reduction in more recent years in coastal and estuarine fisheries reflects widespread measures to reduce exploitation in a number of countries. At the beginning of the time-series about half the catch was taken in coastal waters and one third in rivers. In 2022, about one quarter of the catch was from estuarine fisheries and three quarters from in-river fisheries.

In North America, the total catch has been fluctuating between 80 and 182 t over the period 2009 to 2022. Around two thirds of the total catch in this area has been taken by in-river fisheries, although it was about half since 2018. The estuarine catch has fluctuated between about $23 \%$ and $44 \%$ of the total catch. The catch in coastal fisheries has been typically less than $10 \%$ of the catch each year with the biggest catch taken in 2013 and 2016 ( 13 t in both years).

In Greenland, the total coastal catch increased steadily from 25 t in 2007 to 56 t in 2015, and has since fluctuated between 26 and 42 t . A small number of salmon have been caught in the estuary near the Kapisillit River (in 2019, 19 salmon, total weight 81 kg ; in 2020 no catch reported, in 2022 one salmon was reported caught). Genetic studies have shown this river stock is very isolated from other stocks in the North Atlantic but is an outgroup of the NEAC phylogenetic group, and
salmon caught in the estuary were exclusively from the Kapisillit River (Krohn 2013 unpublished; Arnekleiv et al., 2019).

### 2.1.2 Catch and release

The practice of catch and release in rod fisheries has become increasingly common. This has occurred in part as a consequence of salmon management measures aimed at conserving stocks while maintaining opportunities for recreational fisheries, but also reflects increasing voluntary release of fish by anglers. In some areas of Canada and USA, the mandatory release of large (MSW) salmon has been in place since 1984. Since the beginning of the 1990s, it has also been widely used in many European countries.

The nominal catches presented in Section 2.1.1 do not include salmon that have been caught and released. Table 2.1.2.1 presents catch and release information from 1991 to 2022 for countries that have records. Catch and release may also be practised in other countries while not being formally recorded or where figures are only recently available. There are large differences in the percentage of the total rod catch that is released: in 2021 and 2022 this ranged from 5\% in France, to $96 \%$ in UK (England and Wales) and UK (Scotland), reflecting varying management practices and angler attitudes among these countries. There are no restrictions on the total numbers of fish that may be caught and released in most countries, although in Ireland some rivers are closed completely to recreational angling owing to low conservation status, whereas there are some daily limits for individual fishers in some Canadian fisheries. For all countries, the percentage of fish released has tended to increase over time. There is also evidence from some countries that larger MSW fish are released in greater proportions than smaller fish. Overall, about 183000 salmon were reported to have been released from rod fisheries around the North Atlantic in 2021 and 2022, similar to the previous five-year mean (approximately 182000 ).

Catch and release is also practised in some commercial salmonid net fisheries, for example in UK (England and Wales) and UK (Scotland), where gears that previously targeted and retained salmon and sea trout, and kept the fish alive until retrieval, are now only allowed to retain sea trout and must release any salmon alive.

Summary information on how catch and release levels, and estimates of post-release mortality rates, are incorporated into national assessments was provided to ICES in 2010 (ICES, 2010).

### 2.1.3 Unreported catches

Unreported catches by year (1987 to 2022) and Commission Area are presented in Table 2.1.3.1 and are presented relative to the total nominal catch in Figure 2.1.3.1. A description of the methods used to derive the unreported catches was provided in ICES (2000) and updated for the NEAC Region in ICES (2002). Detailed reports from different countries were also submitted to NASCO in 2007 in support of a special session on this issue. There have been no estimates of unreported catch for Russia since 2008, for Canada in 2007 and 2008, and for France since 2016. The unreported catches for Canada for 2009, 2010 and since 2019 are incomplete as estimates are not available for all regions. There are also no estimates of unreported catch for Spain, where total catches are typically small.

In general, despite the methods used by each country to derive estimates of unreported catch remaining relatively unchanged, incompleteness and inconsistencies in annual reporting mean that comparisons over time may not be appropriate (see Stock Annex). Over recent years, efforts have been made to reduce the level of unreported catch in a number of countries (e.g. through improved reporting procedures and the introduction of carcase tagging and logbook schemes).

The total unreported catch in NASCO areas in 2021 and 2022 were estimated to be 163 and 202 t , respectively. The unreported catch in the NEAC area in 2021 and 2022 were estimated at 134 and 174 t , respectively, and those for West Greenland were 10 t in both years and the NAC area were 19 and 18 t , respectively. The 2021 and 2022 unreported catches by country are provided in Table 2.1.3.2 It is not possible to fully partition the unreported catches into coastal, estuarine and inriver areas.

Summary information on how unreported catches are incorporated into national and international assessments was provided to ICES in 2010 (ICES, 2010).

### 2.2 Farming and sea ranching of Atlantic salmon

### 2.2.1 Production of farmed Atlantic salmon

The estimate of farmed Atlantic salmon production in the North Atlantic area for 2021 was 1990 kt , and the provisional estimate for 2022 was 1938 kt . These are increases on the production for $2020(1775 \mathrm{kt})$ and the previous five-year mean ( 1750 kt ). The production of farmed Atlantic salmon in this area has been over one million tonnes since 2009 (Table 2.2.1.1 and Figure 2.2.1.1). Norway continues to produce the majority of the farmed salmon in the North Atlantic (77\%), followed by UK (Scotland; 10\%). Farmed salmon production in 2021 and 2022 were above the previous five-year mean in all countries with the exception of Ireland. Data for UK (Northern Ireland) since 2001 and data for east coast USA since 2012 are not reported to ICES, as the data are not publicly available. This is also the case for some regions within countries in some years.

Worldwide production of farmed Atlantic salmon has been over one million tonnes since 2001 and has been over two million tonnes since 2012. It is difficult to source reliable production figures for all countries outside the North Atlantic area and as data for 2021 and 2022 are not available, the Working Group has used 2020 data for some countries and assumed the same levels of production for 2021 and 2022 (FAO Fisheries and Aquaculture Department database), to estimate worldwide production. The total worldwide production in 2021 was provisionally estimated at around 2965 kt , and 2912 kt in 2022 (Table 2.2.1.1 and Figure 2.2.1.1), which were higher than in $2020(2757 \mathrm{kt})$ and the previous five-year mean ( 2641 kt ). Production of farmed Atlantic salmon outside the North Atlantic is estimated to have accounted for one third of the worldwide total in 2021 and 2022 and is still dominated by Chile ( $80 \%$ ). Atlantic salmon are being produced in landbased and closed containment facilities around the world and the figures provided in Table 2.2.1.1 may not include all countries where such production is occurring.

The worldwide production of farmed Atlantic salmon in 2022 was over 4000 times the reported nominal catch of wild Atlantic salmon in the North Atlantic.

### 2.2.2 Harvest of ranched Atlantic salmon

Ranching has been defined as the production of salmon through smolt releases with the intent of harvesting the total population that returns to freshwater (harvesting can include fish collected for broodstock) (ICES, 1994). The release of smolts for commercial ranching purposes ceased in Iceland in 1998, but ranching with the specific intention of harvesting by rod fisheries has been practised in two Icelandic rivers since 1990 and these data are now included in the ranched catch (Table 2.1.1.1). A similar approach has been adopted, over the available time-series, for one river in Sweden (River Lagan). These hatchery-origin smolts are re-leased under programmes to mitigate for hydropower development schemes with no possibility of spawning naturally in the wild. These have therefore also been designated as ranched fish and are included in Figure 2.2.2.1. In Ireland, ranching is currently only carried out in a small number of salmon rivers.

The total harvest of ranched Atlantic salmon in countries bordering the North Atlantic in 2021 and 2022 were 20 and $23 t$ (Iceland and Sweden; Table 2.2.2.1; Figure 2.2.2.1) with the majority of catch taken in Iceland during both years. The total harvest was $23 \%$ below the previous five-year mean ( 30 t ). No estimates of ranched salmon harvest are provided for Ireland or UK (Northern Ireland) where the proportion of ranched fish in the catches are more difficult to assess. However, in both instances ranched catches are considered to be an insignificant proportion of the overall harvest.

### 2.3 NASCO has asked ICES to report on significant, new or emerging threats to, or opportunities for, salmon conservation and management

This section answers question 1.2 of the ToRs, providing updates with regard to understanding of effects of Covid-19, threats pertaining to infectious salmon anaemia (ISA), red skin disease (RSD), sea lice, Gyrodactylus salaris and offshore fish farming in Norway, and opportunities pertaining to the ongoing development of model-based estimates of homewater returns in France, and a genetic parentage study revealing that salmon caught and released had a demonstrable reproductive success.

### 2.3.1 Impacts of COVID-19

In Ireland, exploitation rates along with their error terms were revised for MSW salmon in 2020 and 2021 to account for reduced recreational angling due to COVID-related restricted movement orders in spring of each year which likely affected fishing effort on MSW stocks.

In Scotland, in order to use the 2020 and 2021 catch data to undertake stock estimation, the catches were first adjusted to account for the reduction in fishing effort due to Covid-19 restrictions. Statistical models were updated in 2022 to include water flow in the relationships, which improved model fits.

Travel to Greenland was restricted in 2021, and three of the participants in the International Sampling Programme were unable to secure travel arrangements. The samplers who were able to secure travel arrangements were successful in sampling the harvest in the communities they were stationed in. Additional samples were also collected by a local resident in Qaqortoq, Greenland, sampling in Nuuk by the Greenland Institute of Natural Resources (GINR) and the Citizen Science program initiated by the GINR. The Sampling program adequately sampled the Greenland harvest in 2021 given these additional efforts.

### 2.3.2 Threats

### 2.3.2.1 ISA noted in farmed salmon in sea-pens in Iceland for the first time

In November 2021 a farmed salmon in a sea-pen in Reyðarfjörður was detected with an Infectious Salmon Anaemia (ISA-HPR-del) viral infection. The virus was also detected in spring of 2022 in a sea-pen in Berufjörður which is about 40 km from Reyðarfjörður and most likely carried between the fjords with an equipment that was moved between these two areas prior to the first ISA identification. The decision was made to remove and slaughter all salmon in both areas and rest all operation for 90 days. Following the detection, a screening of ISA was carried out in 4660 samples from 14 different sea-pens in the East fjords along with 517 samples from three smolt facilities in 2022, all of which came out negative. ISA has caused problems in aquaculture in several countries since it was first discovered in Norway 1984, but this is the first time the virus has been detected in Iceland.

### 2.3.2.2 Update on Red Skin Disease

Various surveillance programmes and awareness-raising campaigns for reporting of RSD have been established or continued in 2021 and 2022. As in 2019 and 2020, several European countries reported Atlantic salmon returning to rivers with RSD in 2021 and 2022 during late spring into summer. While the majority of recorded cases in Ireland are observed in 1SW salmon, this is not the case elsewhere in Europe (notably UK (Scotland) and northern European countries) where RSD is principally observed in MSW stocks. This may be a consequence of the Irish stocks being predominantly 1SW. RSD was not reported in Greenland, Canada or the USA.

### 2.3.2.3 Update on sea lice investigations in Norway

The surveillance program for sea lice infections on wild salmon postsmolts and sea trout at specific localities along the Norwegian coast continued in 2021 and 2022 (Nilsen et al. 2021, 2022). Activities in the field included trawling for salmon postsmolts in fjords and coastal areas, nearshore traps and nets catching sea trout/arctic char, and sentinel cages with smolts placed at various locations. The field examinations were conducted in two periods; an early period covering the migration period of salmon postsmolts, and a period one week later focused on sea trout infection. As in previous years, the field activities in the surveillance program were partly based on predictions from the hydrodynamic model for spreading and geo-graphic distribution of salmon louse larvae. Field sampling was directed to areas where the model predicted high densities of infective salmon louse copepodites in the smolt migration period.

In 2021, in general, the surveillance program demonstrated varying infection pressure along the coast during the postsmolt migration period. In the southernmost counties (Production area 1), an area with little salmon farming, low levels of salmon louse infections were observed. In southwestern Norway, county Rogaland data indicated low to moderate infection pressure in the salmon postsmolt migration period. In parts of Vestland county (Hardangerfjord and Sognefjord) infection levels on outmigrating salmon postsmolts were relatively high with up to $86 \%$ (Hardangerfjord) and $83 \%$ (Sognefjord) of the fish having $>0.1$ sea louse per gramme fish in some weeks in these fjords. Further north, in Romsdalsfjord lice levels were somewhat lower. In two weeks of trawling the proportion of fish with lice levels $>0.1$ louse $/ \mathrm{g}$ was $23 \%$ and $17 \%$. In Trondheimsfjord, in the middle part of Norway, trawling for postsmolts was conducted in weeks 19-26. The proportion of fish with $>0.1$ lice $/ \mathrm{g}$ varied from $2-31 \%$. In the three northernmost counties lice levels were generally low in 2021, as in earlier years. The sea lice situation on the fish farms did not change significantly compared to 2020, though the level of motile lice was reduced compared to 2020. The average number of adult female sea lice was similar to the previous year. The number of chemical treatments (719) was on the same level as in the last years, as was other methods of treatment (Sommerset et al. 2022).

In 2022, in general, the surveillance program, as in earlier years, demonstrated varying infection pressure along the coast during the postsmolt migration period in 2022. In the southernmost counties (Production area 1), an area with little salmon farming, low levels of salmon louse infections were observed. In southwestern Norway, county Rogaland data indicated low to moderate infection pressure in the salmon postsmolt migration period. The prevalence of sea lice on postsmolts caught in trawls was $53 \%$ in the first week of trawling, and dropped to $40 \%$ in the last two weeks. The proportion of fish with $>0.1$ louse/g varied between $11 \%$ and $45 \%$ in the different weeks. In Hardangerfjord, Vestland county, the infection levels were higher and the prevalence of sea lice on trawl-caught postsmolts increased from $30 \%$ in the first week of trawling (week 19) to $100 \%$ in the last week (week 22). The proportion of fish with $>0.1$ lice/g increased from $8 \%$ in the first week to $94 \%$ in the last week. In the Sognefjord the prevalence of sea lice on migrating postsmolts varied between $72 \%$ and $100 \%$ in weeks 21 to 24 . The proportion of fish with $>0.1$ lice/g varied between $35 \%$ and $92 \%$ in the different weeks. Further north, in the Romsdalsfjord, lice levels on postsmolts were lower, and lower than in 2021. In the area outside the

Trondheimsfjord prevalence was relatively low during the period of trawling, with prevalence increasing from $5 \%$ in the first week of trawling to $23 \%$ in the last week. The numbers are similar to what has been observed in previous years. In the three northernmost counties lice levels were generally low in 2022, as in earlier years. In fish farms, sea lice levels were comparable to 2021, and the five year period 2016-2020. The average number of adult female sea lice was 0.15 , similar to previous years. The number of chemical treatments was on the same level, but the use of other methods (thermic, mechanical etc.) increased (Sommerset et al. 2023).

### 2.3.2.4 Gyrodactylus in Norway

In November 2022 one of the previously infected clusters of rivers ("the Skibotn region") was declared free of the parasite Gyrodactylus salaris. This declaration was made because no parasites had been found in salmon samples taken yearly in the rivers since they were treated with rotenone for the last time in 2016.

The Driva river has been treated with chloramine against G. salaris in 2022. Chloramine is a new treatment that will kill the parasite but not the fish if administered in the correct dosage, eliminating the problems created by rotenone killing all the fish in the river. The treatment will continue in 2023. The smaller rivers in this region was treated with rotenone in 2022, and a new treatment is planned in 2023.

At present, only the Drammen region has not been treated against the parasite, because of the complexity of the water basins, and the number of infected rivers in Norway is decreasing.

### 2.3.2.5 Offshore Fish Farming in Norway

In Norway, plans are under development for opening offshore areas for aquaculture. A number of suggested areas along the coast have been evaluated for suitability for farming of salmon, and also for potential conflict other natural resources such as deep-sea coral reefs and spawning areas for marine species, as well as other activities that may use these areas such as fishing. Through a formal consultation process with a number of institutions and agencies many of the initially proposed areas were excluded and three areas were selected for further evaluation: one off southwest Norway, one area in Mid-Norway and one in northern Norway (http://www.fiskeridi-rektoratet.no/Akvakultur/Dokumenter/Rapporter/anbefaling-av-tre-omrader-for-havbruk-tilhavs). Depending on the technology being developed for the offshore fish farms, the level of production in the areas, and their proximity to migration routes of wild postsmolts, aquaculture in these areas may have an effect on outmigrating postsmolts from the rivers.

### 2.3.3 Opportunities

### 2.3.3.1 Estimating homewater catches and returns in France

In the context of the WGNAS benchmarking process, France has identified the need to review the models used to provide time-series (1971 onwards) of homewater catches and adult re-turns at the national level. A new integrated hierarchical Bayesian model is currently under development that makes the best use of the available data and expertise, while accounting for regional specificities of fisheries and population dynamics. The model integrates various sources of data such as catches of estuarine net fisheries and freshwater angling fisheries, but also estimates of abundances at regional and river scales as well as surface area of production. Regional expertise was used to make assumptions on time-trends of harvest rates, de-pending on the fishery and the sea age class considered. The results provide new insights on the abundance of adults returning to homewaters and on associated harvest rates, both on a regional basis and aggregated at the national level. The decrease of 1SW adults is estimated to be less severe than that which the run-reconstruction model has estimated so far whereas no major changes were observed
between the estimates for MSW returns from the two models. The new approach still needs to be validated and the new estimates are expected to be used for the Working Group's assessment in 2024.

### 2.3.3.2 Effect of Catch-and-Release and temperature on reproductive success on a Quebec river

A new project investigating the effect of catch-and-release and temperature at release on reproductive success of Atlantic salmon has been conducted in Quebec, Canada (Bouchard et al. 2022). This project was motivated by the fact that while this conservation practice is increasingly common and usually cause low mortality rates (Van Leeuwen et al. 2020), its effects on the reproductive success of caught-and-released fish are poorly understood. In this project, the relative reproductive success of caught-and-released to non-caught salmon was compared and the effect of temperature at release was tested. Molecular parentage analysis to link parents with their young-of-the-year progeny shows that at least $83 \%$ of caught-and-released salmon successfully reproduced, including fish that have been released in water warmer than $20^{\circ} \mathrm{C}$. However, the reproductive success of caught-and-released female salmon was only $73 \%$ of the reproductive success of non-caught salmon. Moreover, the increasing temperature did not affect the reproductive success of released fish. These findings should be useful for evaluating the risks and benefits of catch-and-release, and for optimizing conservation practices used for the preservation of Atlantic salmon populations.

### 2.4 Provide information on causes of variability in return rates between rivers within regions in the North Atlantic

Annual estimates of marine return rates of Atlantic salmon in the North Atlantic have been compiled and updated annually by the ICES Working Group on North Atlantic salmon. There are 35 rivers in the Northwest and Northeast Atlantic with monitoring data that provides estimates of return rates of wild outmigrating salmon smolts to adult returns (Figure 2.4.1). This is supplemented by data from 28 rivers with hatchery smolt-to-adult return rates. The datasets cover the period from the 1969 to 2019 smolt migration years. Temporal coverage is sparse for a number of the rivers but 37 datasets including wild and hatchery origin smolts have a temporal coverage of 20 or more years (Figure 2.4.2).

Rivers with return rates reported as 1SW, 2SW (or MSW) returns are categorized as MSW rivers whereas rivers with return rates reported as 1SW only are categorized as 1SW rivers.

Return rates are expressed as the ratio of returning first time spawning salmon to outmigrating salmon smolts for the smolt migration year. Estimates of return rates are provided for one-seawinter (1SW), two-sea-winter (2SW or MSW), and for some series for the sum of first time spawning salmon.

- RR. $1 S W_{y}=1 S W_{y+1} /$ Smolts $_{y}$ representing returns rates to 1 SW first time spawners
- 
- $\quad R R .2 S W_{y}=2 S W_{y+2} /$ Smolts $_{y}$ representing returns rates to 2 SW first time spawners, or
- $\quad$ RR. $A l l_{y}=\sum_{k} k S W_{y+k} /$ Smolts $_{y}$ representing returns rates to first time spawners of all sea age groups ( $k$ ) for the smolt migration year $y$.

The return rates are estimated from the point where smolt and returning adult abundances are assessed and therefore represent the outcome of marine and estuarine fishing and non-fishing related mortality.

It is not possible to speak about marine return rates for Atlantic salmon without considering the interaction of marine survival and sea age at maturity processes. Return rates are the product of sea survival rates (S1, S2,..) and the probability of maturing ( $\mathbb{p}$. mat』_1, ...) at a given sea age:

A number of factors at local, regional, and continental scales, that potentially fluctuate over time, can result in variations in return rates from monitored rivers within and among regions assessed by ICES.

### 2.4.1 Data Considerations

Smolt and adult return monitoring programs most often occur at freshwater monitoring sites. There may be important losses of smolts in the freshwater portion of the river during the downstream migration of smolts and the mortality in the freshwater phase may be important in some rivers and regions, with factors dependent upon the geography of the river systems, predator communities, and anthropogenic stressors (Newton et al. 2019; Flávio et al., 2020; Thorstad et al., 2012; Belletti et al., 2020). An illustration of these high mortalities can be found in Stevens et al. (2019) where they modelled the survival to ocean entry of hatchery origin smolts stocked at various points above the multitude of dams in the Penobscot River (USA) and concluded that over a 43 year period of stocking, only $39 \%$ of the smolts stocked survived to ocean entry.

Losses of adult salmon returning to rivers may also occur in proximity to their natal rivers or in the river itself downstream of the assessment facility and this will have consequences on the calculation of return rates. Standardizing the return rate reporting as returns of adults to freshwater is much easier than attempting to correct for the freshwater location of the smolt monitoring site. Survival rates of smolts through freshwater below the monitoring sites cannot be easily corrected as the rates can be highly variable among rivers and years and estimates from acoustic tagged smolts may not be representative of survival rates of untagged and unmanipulated animals (Vollset et al., 2020).

In the calculation of return rates, the assumption is made that adult survivors return to the rivers from which they emigrated as smolts. The exchange of adults between populations via dispersal (also known as straying) in Atlantic salmon occurs to varying degrees due to a variety of factors including growing conditions, water temperature and flow, size of watersheds and salmon abundance, and metapopulation structure (Birnie-Gauvin et al. 2019; Lamarins et al 2022). Unbalanced emigration and immigration can skew estimates of return rates of local populations with some examples of populations with greater than expected return rates (sometimes exceeding $50 \%$; e.g. Oir in France). A higher rate of emigration than immigration, on the other hand, would result in an underestimation of marine survival. Differences in population size (larger
populations provide more immigrants to smaller adjacent populations for a given dispersal rate), river attractivity (e.g. due to chemical attraction to congeners, collective behaviour, and/or the influence of river discharge), and human activities can all influence unbalanced dispersal (see Keefer and Caudill 2014; Bett et al 2017 for review). Smolts from hatcheries, for example, stray more than wild fish (Quinn, 1993; Nilsen et al. 2022b). Thus, the expected return rate of a population can be affected not only by management practices (such as restocking), but also by those of its neighbours. Dispersal is also likely to be influenced by individual traits (e.g. sex-biased dispersal, age at river/sea, genetic) and can impact comparisons of return rates between sea age.

### 2.4.2 Genetics and equilibrium population considerations

Atlantic salmon in the North Atlantic are structured into more than 2000 genetically discrete populations distributed in watercourses flowing towards the North Atlantic Ocean (Verspoor et al., 2007). Several genes are associated with adaptation in Atlantic salmon, including genes that influence growth rates, age and size at maturity, run timing, and immune function among many (Barson et al. 2015; Aykanat et al. 2019; Cauwelier et al. 2018; Pritchard et al. 2018; Sinclair-Waters et al. 2020; Dionne et al. 2007; Gutierrez et al. 2015).

An attempt to assess the extent of the genetic determinants of marine return rates of Atlantic salmon was inconclusive. Bourret et al. (2014) examined differences in allelic and genotype frequencies between smolts and returning 1SW salmon from two populations for two cohorts going to sea and did not find significant patterns of selective mortality; they concluded that it was more likely that selection caused small changes in allele frequencies among many co-varying loci rather than a small number of changes at loci with large effects.
Atlantic salmon in the North Atlantic exhibit substantial variation in the age and size at maturation both within and among populations (Fleming, 1996). This is regarded as an evolutionary adaptation to varying environmental conditions that maximizes reproductive success (Good and Davidsen, 2016). The maturation process is influenced by the interactive effects of genetic and environmental factors (Thorpe et al., 1998; Czorlich et al., 2018; Mobley et al. 2021).

There are broad regional patterns in the proportions at sea age of first time spawners in the North Atlantic; for example, salmon returns to the Newfoundland and to Ireland have large proportions of first time spawners as 1SW salmon in contrast to the USA region and Norway that have proportionally more MSW first time spawners (Figure 2.4.3).

Return rates are expected to differ between rivers and regions based on the dominant sea age at maturity of the females. MSW salmon are larger bodied and the MSW females have substantially more eggs per fish (twice or more) than the smaller bodied 1SW salmon females (Fleming, 1996). The generational replacement of an individual female spawner depends on the combination of the fecundity of the female salmon, freshwater egg to smolt survival rate, and cumulative smolt to returning female marine survival rate. For similar egg to smolt survival rates, a population dominated by 1SW female sea age at maturity requires a higher marine survival rate for replacement than a population characterized by 2 SW females, because the 2 SW salmon female has individually more eggs. Both life-history types require a higher marine survival rate for replacement if freshwater survival rate declines.

### 2.4.3 Regional variations and differences in return rates

Return rates of wild salmon smolts in the Southern NEAC regions are generally higher than those of the Northern NEAC regions, and both are higher than return rates of regions in NAC (Figure 2.4.4). The differences between continental complexes are also noted in the hatchery origin smolt return rates. In both continent complexes and smolt origin type, the return rates to
first time spawners are higher in populations dominated by 1SW salmon compared to the return rates of the MSW dominated rivers of those regions. The return rate over all years and regions of 1 SW type rivers has a median value of $5.2 \%$ in NAC $(0.6 \%$ to $15 \%$ range $)$, and almost double that value at $9.4 \%$ in Southern NEAC ( $4.3 \%$ to $26.9 \%$ range). Return rates to 2 SW (or MSW spawners) are lowest again in NAC, at a median value of $2.0 \%$ ( $0.4 \%$ to $15.7 \%$ range), higher in Northern NEAC at $4.5 \% ~(0.3 \%$ to $22.9 \%$ ) and highest in Southern NEAC rivers at a median of $6.5 \% ~(0.3 \%$ to $46.7 \%$ ) (Figure 2.4.4). River-specific return rates are highly variable among monitored rivers with general characteristics consistent with the sea age at maturity characteristics of the stocks and the continent of origin patterns (Figure 2.4.5).

The temporal trends in return rates in regions are variable. In NAC there is general declining trend over the 1980s to the 2000s in the return rates to the Quebec region contrasted to increased return rates to rivers for 1 SW salmon in the Newfoundland region (Figure 2.4.6). In NEAC, there is an obvious decline in returns rates for Ireland and UK (Northern Ireland), and in UK (England and Wales), there is a recent decline trend in the 1SW and an increasing trend in the MSW return rates. The declining trend in return rates to 1SW salmon in Norway has occurred from the 1980s to 2000 and levelled off since (Figure 2.4.7).

The trends in regions are not representative of all rivers within those regions. Increased re-turn rates to freshwater in some monitored rivers in Newfoundland region after 1992 are attributed to the closure of the homewater marine commercial fisheries whereas in other rivers, return rates declined further after the commercial fishery closure (Figure 2.4.8). In the NEAC areas, riverspecific return rates for wild salmon are equally variable among rivers and regions. With few exceptions, the general pattern is a decline in return rates to 1 SW salmon and for the overall smolt cohort across all rivers from Iceland to Norway, with exception of the rivers in UK (England and Wales) and UK (Scotland). The strongest decline has occurred for the 1SW salmon return rate, and much less for the MSW return rate (Figure 2.4.9).

### 2.4.4 Factors contributing to variation in return rates

A number of studies and reviews over the past two decades have considered the potential factors and mechanisms that modify marine survival of Atlantic salmon (Cairns, 2001; Crozier et al., 2003; Russell et al., 2012; Forseth et al., 2017; Thorstad et al., 2021; Gillson et al., 2022). Overall, these studies point to the interactions and inter-dependence of the different ecosystems that anadromous salmon occupy and that shape their life histories. Marine survival in Atlantic salmon can be influenced by a range of factors associated with individual outmigrating smolt characteristics (size, condition, genetics), the rearing environment of the juveniles (natural vs. captive rearing), and local and broad-scale ecosystem conditions including physical attributes of the receiving environment, prey and predator communities. In addition to these are the diverse anthropogenic stressors to salmon that differ across the species distribution range.

A large component of the inter-river variation in return rates within the same year are most likely attributable to local and regional variations in factors that affect the early phase of the marine migration and survival whereas the long-term temporal patterns of return rates are most likely determined by the combination of local, regional and North Atlantic factors acting throughout the time of salmon at sea. It is probably a given that predation is the final cause of the death of an individual fish but the factors that lead to it being predated upon may be associated with stresses at an earlier time and location of its life history. These carryover effects can originate in freshwater, in the early phase of the marine migration, and up to the point of return to rivers as potential spawners.

### 2.4.4.1 Carryover effects from freshwater

Survival of smolts at sea is in part related to the freshwater life stages and therefore not independent of smolt characteristics (McCormick et al., 2009; Russell et al., 2012). Compromised survival from stressors in freshwater may manifest itself once the smolts migrate to the sea and although death may occur in the marine environment, the underlying factor that compromised the survival may have originated in the freshwater habitat. As these factors initially occur in freshwater, large differences in their effects on return rates among rivers within a region, and among regions and continental areas may be expected.

Smolts are particularly vulnerable to predation due to their relatively small body size and predation during the first months at sea is probably the most important source of mortality affecting the abundance of salmon populations (Hansen et al., 2003; Friedland et al., 2012; Thorstad et al., 2012). Larger smolts have a higher probability of returning to rivers than smaller smolts due to their better condition and faster growth which seems to favour survival by providing greater resilience to predation and inhospitable environmental conditions (Gregory et al., 2018, 2019). If traits, such as larger body size, have fitness benefits that are heritable, then this would contribute to high between stock variability in return rates.

The timing of smolt migration is crucial to the survival of Atlantic salmon at sea and it is regarded as an adaptation to the prevailing environmental conditions in an area (McCormick et al., 1998; Russell et al., 2012). Possible changes in the run-timing of smolts as a result of environmental variability are, therefore, a concern because of the possible temporal mismatch with optimal conditions for early post-smolt growth and survival. Given the potential for a high degree of congruence in smolt run-timing in particular areas such impacts might be expected to be manifest over rivers in a region.

The stresses of fish passage around and through obstructions (e.g. hydro dams) can also result in lower survival. Stich et al. (2015a, b) estimated that the smolt survival through estuaries was decreased by up to $40 \%$, dependent on the number of dams passed during freshwater migration, highlighting the carryover effects of dams and stress of passage on survival of Atlantic salmon smolts during estuary migration. Stress from passage through turbines or over spillways can also lead to increased predation and disease (Odea, 1999). These stressors would be spatially local within rivers and add to the variability among rivers in a region.

Juvenile salmon in freshwater exposed to sublethal concentrations of contaminants, such as en-docrine-disrupting chemicals, may have compromised survival at sea (McCormick et al., 1998, 2009; Fairchild et al., 2002, Moore et al., 2003, Waring and Moore, 2004). Sources of these compounds may include agriculture, sewage, pesticide spraying and industrial effluents. Industrial developments would be most important in the southern regions of NAC, potentially throughout S-NEAC, and the southern areas of N-NEAC.

Acidification of freshwater resulting from depositions of airborne pollutants may affect Atlantic salmon directly. The effects are related to reduced pH and high levels of aluminium, the latter being mobilized from soils and its increased solubility in water as pH is reduced. Even shortterm episodic exposure in freshwater to aluminium at moderate acidification can reduce marine survival (Staurnes et al., 1996; McCormick et al., 2009; Liebich et al., 2011; Thorstad et al., 2013). Acidification stress on freshwater systems is most important in areas with poor buffering capacity of the underlying geology of the watersheds.

### 2.4.4.2 Carryover effects from estuarine and nearshore areas

Marine aquaculture of both finfish and shellfish can interact with and affect the environment occupied by Atlantic salmon. Pathogens and parasites are two aquaculture related stressors that can have delayed effects on survival of salmon. Enhanced sea lice burdens on salmon smolts that migrate through or proximate to aquaculture producing areas can result in a delayed mortality
of the fish at a time and location distant from the initial infection area. Although Atlantic salmon marine aquaculture occurs in a large number of countries of the North Atlantic area (ICES 2021a), to date salmonid aquaculture is restricted to the coastal areas that provide the appropriate temperature (ice-free), salinity ranges, and flushing capabilities; the impacts would be particularly important on salmon populations that undertake migrations proximate to these production areas.

### 2.4.4.3 Geographic scale effects

Considering the diverse geological and glacial history of the more than 2000 rivers in the North Atlantic occupied by Atlantic salmon, it should not be surprising that the nearshore and coastal receiving environments of seaward migrating salmon would be physically and biologically diverse and heterogeneous. Some rivers empty directly into a saline environment (e.g. Saint-Jean River Canada, Lefèvre et al., 2012), in contrast to other rivers with long, wide and relatively shallow bays (Miramichi River, Chaput et al., 2018), to complex deep and saline fjords (Dempson et al., 2011; Thorstad et al., 2012; Bjerk et al., 2021).

Estuary and nearshore habitat are not generally occupied or otherwise used for rearing by salmon smolts and passage through these areas may be rapid, i.e. a matter of days to a few weeks (Lacroix et al., 2004; Hedger et al., 2008; Halfyard et al., 2012; Renkawitz et al., 2012; Chaput et al., 2018). In complex nearshore environments, the time to exit these areas is longer, 29 days or 36 days in a fjord-like system of approximately 30 km and 50 km axial length, respectively (Dempson et al., 2011; Bøe et al., 2019). The extent to which this residency time is related to feeding opportunities or environmental constraints (e.g. cold water) is not known. While in these nearshore areas, smolts can be exposed to enhanced sea lice densities in areas of aquaculture production. If the smolt migration window through these areas is extended, they may be at a greater predation risk. Avian and fish predator communities in the estuarine and nearshore areas (e.g. Striped bass in Canada, Gibson et al., 2015; Daniels et al., 2018; avian predators, Hawkes et al., 2013; Dieperink et al., 2002) can be very different across the range of salmon rivers in the North Atlantic, contributing in part to the variations in reported return rates.

### 2.4.5 Effects at North Atlantic scale

The consensus view is that marine survival and production of Atlantic salmon in the North Atlantic is not density-dependent.

### 2.4.5.1 Bottom up effects (prey)

Correlations between survival and growth during first summer and winter at sea suggest food resources in quantity and quality may be a limiting factor for some populations. However, variable environmental conditions in the ocean, rather than competition-induced shortages, have been hypothesized to influence marine growth more strongly (Peyronnet et al., 2007). Friedland et al. (2009) found that survival of post-smolts in the Northeast Atlantic was positively associated with plankton and possibly post-smolt food abundance and these prey abundances had declined since the 1970s. Several studies have reported on of ecosystem changes resulting in reduced prey quality including capelin in the Labrador Sea (Renkawitz et al., 2015) and Atlantic herring in the Gulf of Maine (Golet et al., 2015). Renkawitz et al. (2015) reported that over the period 1968 to 2008, the mean energy density of capelin, a key forage species in the North Atlantic, decreased approximately $34 \%$ resulting in substantially reduced energy consumption by Atlantic salmon over time. Altered forage conditions can manifest themselves as variations in size and body condition, as well as on survival and population abundance (Mills et al., 2013; Renkawitz et al., 2015).

Atlantic salmon at sea occupy the upper pelagic area and may compete with other pelagic species for food. In the Northeast Atlantic, salmon occupy similar habitat at times to Atlantic herring
and Atlantic mackerel, two species whose abundances exceed that of salmon by several orders of magnitude and that are important predators on zooplankton, a prey item shared with salmon during early marine life. Utne et al. (2021) indicated that there was a low diet overlap between post-smolts and planktivorous pelagic species in the Northeast Atlantic and there was no correlation between the abundance or survival of salmon from key index rivers and the abundance of pelagic fish.

Olmos et al. (2020) examined the environmental drivers and the demographic mechanisms of the widespread decline of marine survival rate in Atlantic salmon in the North Atlantic Ocean for the 13 stocks units from the NAC and Southern NEAC complexes. A life cycle model was used to investigate whether the temporal variations in the post-smolt survival were best explained by environmental variations encountered by salmon during the early post-smolt phase when salmon use transitional habitats, or during the later phase of the first year at sea when salmon of different origins concentrate in common foraging areas. Results show a strong coherence in the temporal variation in post-smolt survival among the 13 stocks units of NAC and Southern NEAC. Synchrony in survival is stronger between stocks within each complex. Temporal variations of the post-smolt marine survival are best explained by the temporal variations of sea surface temperature (negative correlation) and primary production (positive correlation) encountered by salmon in space-time domains corresponding to late summer/early autumn feeding areas. Those findings support the hypothesis of a response of salmon populations to large-scale bottom-up environmentally driven changes in the North Atlantic that can simultaneously affect several populations originating in distant continental habitats. Also, ecological drivers and/or mechanisms could be different between NAC and Southern NEAC populations in relation to partially different migration routes at sea.

### 2.4.5.2 Top-down effects (predation)

The distribution of potential predators is not homogenous in the North Atlantic, with large numbers in discrete colonies of seabird predators and seasonal distributions of potential fish predators (e.g. Atlantic bluefin tuna) that are limited by sea temperatures. Interactions between marine mammals and salmon populations are not well understood because predation offshore is difficult to detect and salmon often comprise a small portion of the diet of marine mammals compared to other prey species.

### 2.4.6 Genetic perturbations associated with domestication

There are multiple examples that show that the return rates of hatchery stocked smolts are lower than the return rates of wild smolts (Figure 2.4.10). Environmental conditions and selective pressures differ between the hatchery and wild environments with the result that hatchery rearing causes plastic and genetic changes to phenotypes that often result in reduced fitness when these fish are released back into the wild (Fraser, 2008, 2016; Perrier et al., 2013). Unfortunately, rapid selection under domestic conditions can create challenges when attempting to supplement natural populations with hatchery-reared fish. Genetic data suggest that stocked fish have often had limited reproductive success (Fontaine et al., 1997; Saltveit, 2006; Milot et al., 2013).

The influx of genes from escaped farmed salmon into populations of wild salmon affects a number of important traits closely connected to fitness (e.g. growth, age at outmigration, sea age, parr maturation, and predator avoidance) (Bolstad et al., 2017; Glover et al., 2017; Solberg et al., 2020; Bolstad et al., 2021, Besnier et al., 2022). In addition, it strongly affects survival probability in the wild for individuals with farmed genetic ancestry (Fleming et al., 2000; McGinnity et al., 2003; Skaala et al., 2012, 2019; Wacker et al., 2021).

Interbreeding between domesticated and wild Atlantic salmon occurs in many parts of its natural range on both sides of the Atlantic (Clifford et al., 1998; Crozier, 2000; Skaala et al., 2006;

Bourret et al., 2011; Karlsson et al., 2016; Wringe et al., 2018). Hence, genetic introgression has the potential of widespread population effects in Atlantic salmon. However, rivers vary in their level of introgression, even on small geographic scale (Karlsson et al., 2016; Wringe et al., 2018; Diserud et al., 2022), and this may therefore have a large influence on local variation in return rates.

### 2.4.7 Conclusion

Variations in return rates of smolts to 1SW, MSW, and the smolt cohort observed among monitored rivers, among regions and continental groups suggest that factors at river-specific, regional and North Atlantic scales interact to affect marine survival rates and maturation schedules. With exception to very specific identifiable factors, such as exploitation of returning spawners in rivers or mortality of downstream migrating smolts through turbines, it is very unlikely there is a single factor that can account for the temporal variations, and in several areas, the declines of wild Atlantic salmon in the North Atlantic.

### 2.5 Provide a summary of the most recent findings of ongoing research projects investigating the marine phase of Atlantic salmon (e.g. SeaSalar, SeaMonitor, SAMARCH, satellite tagging at Greenland

The Working Group is aware of a number of large-scale collaborative projects investigating the marine phase of Atlantic salmon across the North Atlantic. These projects are ongoing and this section introduces these projects and provides updates on status and preliminary results. Information was provided directly by Working Group members involved in the pro-jects.

### 2.5.1 Atlantic Salmon Federation's Acoustic Tracking

Since 2003 the Atlantic Salmon Federation and its partners have tracked more than 4500 smolts (acoustic tags) and 600 kelts (acoustic and satellite tags) from several Gulf of St Lawrence (GoSL) rivers through estuaries, bays, the GoSL and into Labrador Sea. This tracking program is designed to monitor the migration of smolts and kelts through the freshwater, estuarine and nearshore environments of the GoSL en route to the North Atlantic (Figure 2.5.1.1). Long-term monitoring programs like this are valuable in that they allow researchers to address a number of topics across a long temporal scales encompasses varying environmental conditions.

Across the 20-year monitoring period, tagged smolt survival through the freshwater environments has generally been greater than $80 \%$ throughout the time-series (Figure 2.5.1.2). Survival for smolts from the Cascapédia and Restigouche rivers through Chaleur Bay (head of tide to the outer Bay) has generally been higher than that of Miramichi smolts migrating through Miramichi Bay. This is particularly noticeable for Northwest Miramichi smolts in recent years. Various studies utilizing these datasets have focused on the role of increased striped bass populations in the areas resulting in decreased survival of Miramichi River salmon smolts (Daniels et al. 2018, Daniels et al. 2019, Brunsdon et al. 2019). Out-migrating smolts and kelts exclusively use the Strait of Belle Isle (SoBI) to enter the North Atlantic, a journey upwards of 700 km . Survival through the GoSL to the SoBI has remained fairly consistent for all populations through the time-series and at approximately the same rate, although a slight decrease over the time-series is noted for the Northwest Miramichi smolts. Collectively these results demonstrate relatively high freshwater survival, moderate GoStL survival with variable rates of survival within estuarine and nearshore environments, which are driven by local conditions.

Tagging operations have been partially supported and enhanced since 2021 with support from the (Environmental Studies Research Fund; Section 2.5.2). Moving forward, tagging by Atlantic Salmon Federation and its partners is expected to continue in the near term to maintain this dataset.

### 2.5.2 Environmental Studies Research Fund

A five year research project focusing on the marine migration of Atlantic salmon in the North Atlantic was funded by the government of Canada's Environmental Studies Research Fund in 2020. The project was titled "Atlantic salmon in the Eastern Canadian offshore regions (ESRF Regions 8 to 15): timing, duration and the effects of environmental variability and climate change" and has over 20 project partners including Indigenous communities, Indigenous organizations, non-government organizations and several provincial and federal government departments. The objective of the project is to determine when, where and for how long Atlantic salmon from three different life stages (juvenile post-smolt, post-spawned kelt and multi-sea winter adults) are in the Eastern Canadian offshore oil and gas regions (ESRF Regions 8 to 15). The project is applying telemetry (acoustic and pop-off satellite tags) and ocean model-ling methods to better understand the migratory behaviour (location and habitat use) of salmon at sea. The results will support regulatory decision-making in Canada's areas of offshore oil and gas activity as well as advance our understanding of the marine phase of Atlantic salmon.
In 2021 and 2022, a total of 2314 smolts and 434 kelts were tagged with acoustic transmitters and an additional 122 kelts were released with PSATs (pop-off satellite tag) from 38 rivers across eastern Canada. PSAT tagged salmon were released at Greenland in 2021 ( 70 salmon) and 2022 ( 114 salmon) as well as an additional 95 salmon with acoustic transmitters in 2022 (see Section 2.5.5). ESRF funds have also supported the deployment of a new network of offshore acoustic receivers that added to the existing infrastructure maintained by project partners (Figure 2.5.2.1). Wave glider and drifter missions were also conducted to improve detection coverage within the area of focus.

Preliminary results from PSAT tags and 2021 and 2022 acoustic tag detections are being compiled. A third year of tagging is schedule for 2023 within eastern Canada and Greenland. Additional glider missions will also be conducted. Oceanographic modelling is underway and data analyses will continue through 2025. Expected project outcomes are:

- Document the occurrence of Atlantic salmon from different rivers entering areas of interest to oil and gas production/exploration activities with an assessment of the timing, duration and areas where this may occur;
- Determine the physical and biological oceanographic processes driving observed salmon migration patterns;
- Develop an Atlantic salmon migration model using oceanographic models and the migration patterns observed by electronically tagged salmon to predicted migration patterns given expected changes in environmental conditions;
- Provision of this new knowledge in a usable form to Indigenous groups, stakeholders, salmon scientists, managers, industry and regulators.

### 2.5.3 Atlantic salmon at sea - factors affecting their growth and survival (SeaSalar)

A research project focusing on salmon at sea and funded by the Research Council of Norway was initiated in Norway in 2018 (https://www.seasalar.no). The four-year project has been extended and will end in August 2023. An important part of the project was to utilize existing
datasets and activities, including salmon collected at sea, genetic material, archival scale samples, survival data, population size data and datasets on other marine species and oceanic ecosystems. This aim has been fulfilled, as a number of existing samples and datasets have been worked up and analysed, and the resulting scientific papers have expanded our knowledge and understanding of the marine phase of the salmon's life cycle. To date, 24 scientific papers related to this project have been published (https://www.seasalar.no/Publications12). These papers have contributed to a better under-standing of oceanic migration routes and feeding areas, both for postsmolts and kelts, diet and feeding of postsmolts in fjords and in the ocean, ocean growth over time for a large number of rivers and variation in life history among rivers and regions. Some of the main findings so far are described below.

Gilbey et al. (2021) analysed a dataset consisting of more than 9000 postsmolts caught in the ocean over many years and coupled catch and effort data to provide a description of the monthly distribution of postsmolts in the Norwegian Sea. Genetic data were available for around 3500 postsmolts, and these were assigned to different regions of Europe, providing data to describe how postsmolts from different regions are distributed in the ocean. The diet and feeding studies by Utne et al. $(2020,2021 \mathrm{a}, \mathrm{b}, 2022)$ showed some diet overlap between postsmolts and other pelagic species such as herring and mackerel, a change in prey composition over time and a reduction in growth for postsmolts around the year 2005, and how this was correlated to reduced influx of Arctic water in the Norwegian Sea. This was also observed in a study by Vollset et al. (2022) who analysed a large dataset of growth data from scale samples of returning spawners to Norwegian rivers. As in the postsmolt studies, 1st year growth dropped for salmon from all regions of Norway, except north, around the year 2005. Rikardsen et al. (2021) compiled a large dataset of satellite tagging of kelts from several countries in Europe, and Greenland, and generated a new map demonstrating both overlap and regional differences in oceanic feeding areas for kelts. During SeaSalar, new data from kelt tagging in rivers in Norway have also been collected and are currently under analysis. In the study by Persson et al. (2022) data from over 500000 scale samples from rod fisheries in Norwegian rivers was analysed to investigate patterns in life-history variation among rivers and region. They identified 141 unique life-history types, and repeat spawners contributed $75 \%$ of that variation.

Collectively, the scientific papers generated from SeaSalar and other projects related to marine survival of Atlantic salmon have significantly increased our understanding of the under-lying mechanisms that influence and regulate the oceanic phase of the salmon's life cycle. By analysing time-trends in parameters such as first year growth at sea, coupled with increased knowledge of how salmon are distributed and relevant data on oceanic conditions, new understanding of large- and small-scale processes have been achieved.

### 2.5.4 SAlmonid MAnagement Round the CHannel (SAMARCH)

The SAlmonid MAnagement Round the CHannel (SAMARCH) project (https://www.samarch.org) was a multiyear project (2017-2023) partly funded by the EU Interreg VA France (Channel) England programme and involving five UK and five French partners. SAMARCH collected scientific evidence to inform the management of salmon and sea trout (salmonids) in the estuaries and coastal waters on both the French and English sides of the Channel. It had four work packages that had the following themes: (1) tracking, (2) genetics, (3) modelling, and (4) communications. SAMARCH did work in four Index Rivers: rivers Frome and Tamar (UK) and Scorff and Selune (France), although some of the work involved stocks from rivers elsewhere around Europe and the Atlantic Basin.

Data generated by SAMARCH include biometric measurements, migration timings, movement observations and growth patterns from scale-reading. These data were collected from 900 juvenile salmonids acoustic tracked in four rivers and estuaries, 314 adult sea trout fitted with Data

Storage Tags in three rivers, 100000 PIT-tagged juvenile salmonids and 24000 observations of their returns in two rivers, genetic sexing of 9500 juvenile salmonids, and reading of over 10000 salmon scales collected since 1971.

To date, SAMARCH staff published 17 scientific papers (https://samarch.org/publication-reports/), supervised two PhD projects and 12 MSc projects to completion, and gave greater than 200 students valuable work experience.

Among the highlights from those outputs concerning Atlantic salmon are:

- New data on salmon growth at sea showing a pan-populations decline in growth during the first summer at sea in the last four decades for smolts of all index rivers;
- Results highlighting that smolts with the highest body size at smolt migration on average have a higher return rate;
- New insights on growth-mediated maturation schedule, with post-smolts that have the higher growth during the first summer at sea have the greater probability to mature as 1SW, and clear differences between sexes with males having a greater probability to mature as 1SW than females;
- New model to estimate adult returns from rod exploitation for all UK (England and Wales) rivers; and
- Improvements to the Bayesian Life Cycle Model proposed for ICES WGNAS annual assessment.

SAMARCH held a closing conference in March 2023. Much of the discussion centred on how the new information generated by SAMARCH could contribute to better management of salmonids around the Channel. Among the issues considered were whether salmonids are sufficiently wellprotected by marine legislation, and if not, whether salmonids might be better protected if they were treated as marine species.

### 2.5.5 Pop-off satellite tagging at Greenland

A primary gap in our understanding of the North Atlantic decline in wild Atlantic salmon is in the ocean phase of their migration and telemetry is a tool that can be used to address this gap. With a better understanding of the spatial and temporal distribution of Atlantic salmon in the marine environment, researchers can begin linking the physical and biological mechanisms that are contributing to mortality. A 5-year pop-off satellite tagging (PSAT) study on Atlantic salmon captured at West Greenland was initiated in 2018 with the goal of mapping the marine distribution and migration patterns for maiden Atlantic salmon and post spawned adults released at West Greenland so that oceanographic features (physical and biological) may be evaluated to assess how they may influence survival.

This is a collaborative research program involving the ASF, Fisheries and Oceans Canada and NOAA Fisheries Service. Additional funding has been provided by Equinor (an international private company invested in oil and gas exploration), the government of Canada's Atlantic Salmon Research Joint Venture (ASRJV) and Environmental Studies Research Fund (ESRF). Kalaallit Nunaanni Aalisartut Piniartullu Kattuffiat (KNAPK), the Organization of Fisher-men and Hunters in Greenland, has also provided logistical support.

Tagging occurred in the southwest of Greenland in 2018, 2019, 2021 and 2022 during the months of September and October. To date, 341 Atlantic salmon have been captured ( $99 \%$ by trolling) and 317 have been tagged and released.

| Tagging Overview |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- |
| $\underline{\text { Tag type }}$ | $\underline{\mathbf{2 0 1 8}}$ | $\underline{\mathbf{2 0 1 9}}$ | $\underline{\mathbf{2 0 2 0}}$ | $\underline{\mathbf{2 0 2 2}}$ | $\underline{\text { Total }}$ |
| Acoustic | 2 | 4 | - | 95 | $\mathbf{1 0 1}$ |
| PSAT | 12 | 20 | 70 | 96 | 198 |
| Double tagged (PSAT and acoustic) | - | - | - | 18 | $\mathbf{1 8}$ |
| Total | $\mathbf{1 4}$ | $\mathbf{2 4}$ | $\mathbf{7 0}$ | $\mathbf{2 0 9}$ | $\mathbf{3 1 7}$ |

Overall, the fork length of tagged salmon ranged from 555-890 mm with an average of 665 mm and whole weight ranged from $1.4-11.0 \mathrm{~kg}$ with an average of 3.7 kg . Approximately $96 \%$ of the tagged salmon were 1SW non-maturing salmon and $74 \%$ were of North American origin, $24 \%$ European origin and $2 \%$ unknown. Preliminary analysis of region of origin suggests that 14 regional reporting groups from North America and four from Europe are represented. Further work on the continent and region of origin analyses is continuing.

Data collection is ongoing as a large number of PSAT tags released in 2022 may still be active and data from acoustic tags detections have yet to be downloaded from all potential receiver units. Pre-programmed pop-off dates were set for the spring following release, but a number of tags pop-off early for a variety of reasons. After pop-off, the PSAT surfaces and transmits it data to the researchers via satellite connections. PSAT pop-offs have occurred across the North Atlantic (Figure 2.5.5.1.) and to date, marine migration data have been collected for over 12000 migration days. Data collected by the PSATs are temperature, depth profiles and light intensity data, all of which can be used to reconstruct the individual migration tracks. Tagging activities are planned for 2023 and data processing and analysis are planned for 2023-2025.

### 2.5.6 SeaMonitor

SeaMonitor was a regional marine research project studying the seas around Ireland, Western Scotland and Northern Ireland. The project was led by the Loughs Agency and supported by eight other research institutions using innovative marine species tracking technology to better understand and protect vulnerable marine life in the region's ocean (including salmon, basking sharks and seals). Funding for the SeaMonitor project has been provided in part by the EU's INTERREG VA Programme (Environment Theme), which is managed by the Special EU Programmes Body (SEUPB). This investment facilitated the deployment of the longest 'fish counter' in Europe with a line of $>100$ acoustic receivers running between Ireland (Malin Head) and Scotland (Islay island; SeaMonitor Main Array) and the use of innovative technologies (e.g. waveglider, autonomous vehicles, programmed tags) to track fish emigrating from local rivers.
Salmon research principally relied on acoustic tagging of smolts by the four main (salmon) partners (Loughs Agency, Agri-Food and Biosciences Institute Northern Ireland, Marine Institute, Glasgow University) across the region (Northern Ireland, Ireland and Scotland). The science objectives included; the development of salmon management plans for the rivers Foyle and Clyde, assessment of early marine migration, directionality and mortality, and the development of marine pathway models for post-smolts exiting the region. Some initial findings have indicated common migratory trajectories for regional smolt groupings detected on the Main Array, a dominant North-Northwest outward migration route for smolts and variable migration speeds/mortality rates between rivers. Integration of the SeaMonitor data with other tracking projects on rivers in the Irish Sea/West Scottish area has added further value to salmon tracking research in
the region (https://www.loughs-agency.org/managing-our-loughs/funded-programmes/cur-rent-programmes/sea-monitor/seamonitor-publications/).

### 2.5.7 SMOLTRACK

SMOLTRACK is a NASCO coordinated, EU-funded project aimed at establishing a strategic salmon telemetry advisory group. Through conducting simultaneous salmon telemetry research projects in multiple partner countries, SMOLTRACK facilitates exchange of knowledge and best practices related to tracking salmon smolts during the early (freshwater, estuarine and coastal) phase of their marine migration. Given the critical importance of this migratory phase for complete life cycle survival rates, the data and knowledge acquired through the SMOLTRACK project from different European salmon populations in distinct habitats, will aid with understanding causes of mortality as well as environmental drivers of migration timing and movement behaviour. Ultimately, the aim of the SMOLTRACK project is to provide an evi-dence-base for supporting management actions implemented to improve salmon conservation practices, such as highlighting potential mitigation measures that may improve survival rates of seaward migrating smolts.

There are numerous partners with established river monitoring site from across Europe. These include the Technical University of Denmark (Rivers Skjern and Storå, Denmark); Centre for Environment, Fisheries and Aquaculture Science (River Tamar and Taff, UK (England and Wales)); Inland Fisheries Ireland (River Erriff, Ireland); Agri-Food and Biosciences Institute (River Bush, UK (Northern Ireland)); General Directorate of Natural Heritage, Environmental Ministry, Galician Government (River Minho, Spain), University of Gothenburg (Rivers Göta älv and Högvadsån, Sweden), Natural Resources Institute Finland (Teno, Finland) and the Marine and Environmental Sciences Centre and University of Évora (Minho, Portugal).

The third iteration of the project, SMOLTRACK III concluded at the end of 2022. A fourth iteration, SMOLTRACK IV, is currently underway.

### 2.6 Provide a summary of the current state of knowledge on freshwater and marine predation by cormorants and impact on stocks

In the North Atlantic region, the great cormorant (Phalacrocorax carbo) and the double-crested cormorant (Nannopterum auritum) can be found, where the latter is only present in North America. The great cormorant consists of two subspecies; Phalacrocorax carbo carbo and P. c. sinensis. They exhibit predominantly a piscivorous diet and P. c. sinensis is likely to pose the greater threat in regards to the predation of salmon.

In Europe, cormorants (principally P. c. sinensis) have increased extensively since the 1980s mainly in the North Sea and Baltic Sea regions. Numbers of this subspecies have increased substantially in Europe (excluding Russia, Belarus, Moldova and Ukraine) from approximately 10 000 breeding pairs in 1970 to approximately 233000 in 2006, though estimates vary depending on subspecies, geographical region and year (FAQ - Nature - Cormorants - Environment - European Commission (europa.eu)). The greatly increased population has led to widespread conflicts throughout Europe, where even mitigation measures and cormorant regulation (Article 9 of the EU Birds Directive, The Birds Directive - Environment - European Commission (europa.eu)) have not been effective in resolving these (EIFAAC, 2022).

In Denmark, there was a rapid increase of breeding pairs of cormorants in the 1990s, from very few to 40000 pairs. The main food was coastal fish and main conflicts were on the coast with
poundnet fishers. Common prey species of cormorants such as cod, flounder, dab and eelpout populations $(\mathrm{Dab}=$ Limanda limanda, $\operatorname{cod}=$ Gadus morhua, flounder $=$ Platichthys flesus, eelpout $=$ Zoarces viviparus), have ostensibly decreased substantially. It is hypothesized that as a result of this, the abundance of breeding cormorant pairs has decreased to around 30000 breeding pairs (Jepsen et al. 2019).

Many studies have been conducted focusing on the impacts of cormorants on fish populations in Denmark. For example, Jepsen et al. (2019) found, from results of 23 individual studies, that a mean of $47 \%$ of smolts (both salmon and trout) are consumed by cormorants over multiple rivers and years. In Denmark, cormorant/smolt studies have been carried out for 20 years and it is noteworthy that when the cormorant breeding population was at its highest with more than 40000 breeding pairs, the rapid rebuilding of the Danish salmon populations took place simultaneously (personal communication, Jepsen). However, after a steep decrease in available prey on the coasts, the cormorants started to forage in Danish rivers, consuming a large proportion of salmon parr. It is hypothesized this reduction in traditional marine prey for cormorants resulted in decreased cormorant abundance but increased predation on salmon in freshwater, and is likely the reason for the stagnation of the recovery of Danish salmon stocks, despite increased and improved spawning and rearing habitats.

A series of predator exclusion experiments were conducted in several Danish rivers and the results showed that winter survival of $0+$ and $1+$ salmon parr increased from $17 \%$ to $50 \%$ when cormorants were excluded (other predators had access) by installing covernets over river stretches (Jepsen, unpublished data, Skarver i vandløb - hvad betyder det for laks og ørred? Fiskepleje.dk). Results from these studies suggest that cormorant predation will lower smolt production and could result in as much as a $75 \%$ decrease in adult salmon runs, a substantial impact on EU-listed salmon in Danish rivers (Habitats Directive, Annex V; The Habitats Directive - Environment - European Commission (europa.eu)). In Europe, the cormorant diet can vary sizeably over time and space, and in particular in relation to the prey availability in freshwater or marine environments, which has led to the conclusion that the effects of cormorant predation on salmon in some areas may be more limited (Lyach and Čech, 2017).

In Sweden and Finland, a similar increase in breeding cormorants has been observed during the last decades. Similarly to Denmark, coastal fish populations have decreased, and therefore shifts in cormorant diet may be expected. In Sweden, results from PIT-tagging in the river Dalälven show (like in Denmark) that trout is more commonly preyed upon by cormorants compared to salmon, particularly in the Baltic Sea (Fågelpredation i Dalälven mynningsområde - en tredjedel av all öring som sätts ut blir uppäten av fåglar | Externwebben (slu.se)). On the Swedish west coast, only a few studies have been conducted focusing on cormorant-prey dynamics. However, it has been suggested that the predation pressure on cod is more of a concern than that on salmon in the marine environment. Some accounts also propose that in west coast rivers, cormorants may be feeding upon salmon (pers. com. K. Lundström, SLU). Reports from Ireland conclude that predation from cormorants (note: carbo subspecies) can also be a problem for salmon stocks in some areas (Kennedy et al., 1988; Flavio et al. 2020). Cormorant predation has also been identified as an issue for grayling populations in some areas of Europe, even leading to local extinctions (Carss and Russell, 2022, Jepsen et al. 2018).

Very few salmonid studies met the criteria for inclusion in a global meta-analysis of the effect of predation from cormorants (multiple Phalacrocorax species) on fish in general (Ovegård et al. 2021). No Atlantic salmon studies were included in this analysis because they did not meet the criteria, and therefore, the range-wide effect of cormorant predation on Atlantic salmon populations remains unclear. More studies are required, and these must be statistically robust, with clear treatment-control setups so that confident conclusions can be made.

In North America, Cairns (1998) reported that Double-crested cormorants (Phalacrocorax auritus) breed along coasts and estuaries in the Atlantic New England states, the Maritimes Provinces, and Eastern Quebec. A few inland colonies are also found in the Gulf region. They forage primarily along the coast but may intrude freshwater habitat during spring runs of anadromous fish. At that time, diets may include a substantial fraction of Atlantic salmon during smolt outmigration in rivers whose runs are supplemented by stocking. At other times, this species feed on a variety of marine and estuarine species. Double crested cormorants leave the region in autumn to winter in the southeastern United States.

Great cormorants (P. carbo carbo) mainly breed in Nova Scotia with a few colonies found in Quebec and Newfoundland. They forage almost exclusively in salt water. Information on their diet is only available for populations on the coasts of Nova Scotia and the Magdalen Islands (Quebec). No salmonids were found in the stomach, vomit or pellets samples from this species.

In 2004 and 2005, Hawkes et al. (2013) conducted experiments to evaluate the effectiveness of non-lethal harassment of Double-crested cormorants to improve smolt survival in the Narraguagus River (USA). Their study highlighted the lack of overlap between the peak migration of smolts (mainly at night) and cormorant presence in the estuary (mainly in the morning). Most mortalities observed (30/127 smolt marked) during the study occurred in the estuary in the morning hours with reduced mortality rate when harassment occurred. A study (Carrier et al., 2016) on a colony of about a thousand breeding pairs of Double-crested cormorants located at the mouth of the Restigouche river (New Brunswick, Canada) found two salmon otoliths out of 441 regurgitated pellets during the 2014 smolt run, suggesting that Atlantic salmon smolts did not make a large part of the diet of these cormorants.

In conclusion, in areas where cormorants have increased, and/or declines in other cormorant prey species abundances have occurred, there is a higher likelihood that salmon will be predated upon. Cormorant predation can have substantial impacts on salmon populations, particularly in areas where salmon populations are already threatened or endangered, but further and more robust studies are required to determine local and widespread effects on salmon populations.

### 2.7 Data Call for NASCO requested information used by the Working Group

The terms of reference from NASCO defines the work of WGNAS. Other than for the catch data, the terms of reference are not specific as to what type of information would be used by ICES to develop the status of stocks.

### 2.7.1 Process for collating catch data

The request for catch data is specific as to the type of information to be compiled:

- provide an overview of salmon catches and landings by country, including unreported catches and catch and release, and production of farmed and ranched Atlantic salmon in 2021 and 2022.

In each Commission Area, the request includes:

- describe the key events of the 2021 and 2022 fisheries (ToR 2.1, 3.1, 4.1)

### 2.7.2 Review of the 2023 Data Call

On 30 January 2023, ICES communicated the Data Call for Atlantic salmon from the North Atlantic to ICES Member Countries. The salmon call was contained within the wider "Joint ICES Fisheries Data call 2023 for landings, discards, biological sample, catch and effort data" (see Data calls (ices.dk)). Subsequently on 16 February 2023, the chair of WGNAS copied the ICES Data Call to members of the Working Group. The Data Call included instructions in a covering letter and a template spreadsheet in Excel as attachments (Annex 7.12.1 WGNAS template.xlsx). The request was for members to return the catch data for 2021 and 2022 to ICES by 10 March 2023.

The Data Call was specific to the compilation of catches as defined in the terms of reference from NASCO. Note also that NASCO requests from parties, as part of the annual reporting, similar information as requested by ICES in the Data Call.

The Data Call should provide data that can be used by WGNAS to address the NASCO request, i.e. for the primary catch tables in WGNAS report (Tables 2.1.1.1, 2.1.1.2, 2.1.1.3, 2.1.2.1, 2.1.3.1, 2.1.3.2, 2.2.1.1, 2.2.2.1, Annex 4; Figures 2.1.1.1a,b, 2.1.1.2, 2.1.1.3, 2.1.3.1, 2.2.1.1, 2.2.2.1). When collated across jurisdictions, the Data Call submissions should be appropriate for NASCO themselves to generate summaries. The future Data Call request would also provide catch data that are used in the North Atlantic wide Life-Cycle Model (LCM, see below).

In previous years, the data requested in the Data Call would have been compiled by members of the Working Group from national working papers and summarized in the report. The ICES Data Call has resulted in more prompt and comprehensive reporting for some countries where in the past the collation of catch data had been difficult and incomplete.

The following country/jurisdiction reports were received:

- NAC: Canada, USA, France (reporting for Saint Pierre and Miquelon);
- NEAC: Iceland, Spain, France, UK (England and Wales), UK (Scotland), UK (Northern Ireland), Denmark, Sweden, Norway, Finland;
- WGC: Greenland.

Some reports were received after the deadline because of issues with the communication of the official request. These have been noted by ICES and the countries, and solutions will be found to make the process more successful in future years.

Data call submissions were not received for the following NEAC jurisdictions with known/historic salmon fisheries or farmed salmon production: Ireland, Russia, Faroe Islands, Portugal, Germany. Equivalent data from Ireland and Faroe Islands were received via national reports to the Working Group. Major salmon stocks in German North Sea-draining rivers are extirpated and now rely on stocking and reintroduction programmes. The Working Group understands there was no commercial catch in Germany in 2022. There may have been a small amount of recreational catch but the amount has not been reported.

The data submitted in March 2023 were reviewed by the Working Group and some issues were identified. Details of the review and proposed changes are outlined in Annex 8.

### 2.8 Progress on developing the Atlantic salmon Benchmark

Following previous discussions at WGNAS 2020 and WGNAS 2021 (ICES, 2020, 2021a), and following the resolutions of the Workshop for Salmon Life-Cycle Modelling (WKSalModel; 5-8 January 2021, remote) (ICES, 2021c: WKSALMODEL), and in preparation of the adoption of the Life Cycle Model (LCM) by WGNAS for stock assessment and provision of multiyear catch advice,
an ICES WGNAS benchmark process was decided. It started in 2022 and will be achieved by end 2023.

WGNAS benchmark scoping meeting held 15-17 November 2022 (hybrid). Objectives were to discuss and agree on the ToR's of the Benchmark, and set the dates for the Data meeting and the Assessment meeting.

The benchmark process should be achieved before the end of 2023, so as the new model can be officially used for assessment, multiple years forecast and catch advice in 2024 (full assessment year). In order to reserve sufficient time between the data meeting and the assessment meeting, and at least two months between the assessment meeting and the end of 2023, the following schedule was decided:

- allocate $1 / 2$ day during WGNAS 2023 to advance preparatory work for the Data meeting
- Data meeting - 3 days (fully remote) during the week June $19^{\text {th }}-22^{\text {th }} 2023$
- Benchmark assessment meeting - 5 days (hybrid), during the week October $23^{\text {th }}-27^{\text {th }} 2023$

In order to advance the preparation of the Benchmark ToR's, resolutions were made during the scoping meeting and further discussed during WGNAS 2023 meeting (ICES, 2022a). Chaired by the benchmark ICES chair Jonathan White, the group agreed on modelling hypotheses and data issues to be reviewed and tested during the benchmark. Based on these discussions, a data call specific for the benchmarking process will be sent in early April 2023 to prepare the data meeting. Tasks have also been assigned to different WGNAS members to advance benchmark work from now to the data meeting.

### 2.9 Reports from ICES expert group and other investigations relevant to North Atlantic salmon

### 2.9.1 WGDIAD

The Working Group on the Science Requirements to Support Conservation, Restoration and Management of Diadromous Species (WGDIAD) provides a forum for the coordination of ICES activities relating to species which use both freshwater and marine environments to complete their life cycles, such as eel, Atlantic salmon, sea trout, lampreys, shads, smelts, etc. The Working Group considers progress and future requirements in the field of diadromous science and management and organizes Expert Groups (EGs), Theme Sessions and Symposia. There is also a significant role in coordinating with other science and advice Working Groups in ICES.
The annual meeting of WGDIAD was held in a hybrid format, both remotely (by WebEx) and inperson, from 20-21 September 2022, and chaired by Hugo Maxwell (Ireland) and Dennis Ensing (UK). There were 17 participants in total from 13 countries who participated in the meeting for at least one of the days. The following topics relevant to Atlantic salmon were discussed:

- International Year of the Salmon (IYS) Synthesis Symposium in Vancouver, Canada, 4-5 October 2022;
- Northern Hemisphere Pink Salmon Experts Group meeting, Vancouver, Canada, 2-3 October 2022;
- A progress report of the work of the Intersessional Sub Group Diadromous fish (ISSG Diad) of the Regional Coordination Groups (RCGs). The subgroup has a coordinating function and identifies data collection needs for diadromous species in relation to the EU data collection regulation;
- A discussion on a formal ICES/WGDIAD link with diadromous fish scientists in the Pacific within organizations such as the North Pacific Marine Science Organization (PICES) and North Pacific Anadromous Fish Commission (NPAFC);
- A report from ICES Assessment Working Group on Baltic Salmon and Trout (WGBAST)

The next meeting of WGDIAD will be held during the 2023 ICES ASC in Bilbao, Spain, 11-14 September - WGDIAD meeting dates to be confirmed.

### 2.10 NASCO has asked ICES to provide a compilation of tag releases by country in 2021 and 2022

Data on releases of tagged, finclipped and other marked salmon in 2021 and 2022 were provided to the Working Group and are compiled as a separate report (ICES WGNAS Addendum, 2023c). In summary (Table 2.10.1a and Table 2.10.1b), approximately 1.50 million salmon were marked in 2021 and 1.12 million in 2022. These were a decrease from the 1.96 million fish marked in 2020. In 2021, the adipose clip was the most commonly used primary mark ( 1.11 million) with around half ( 0.465 million) of these marked and released in the Russian Federation. The adipose clip was also the most commonly used ( 0.777 million) primary mark in 2022 with the decrease between years related to no data being provided from Russia. Coded wire microtags (CWT) were the next most common primary mark with similar numbers as reported for the 2020 tagging season ( 0.196 million). In both years, most marks were applied to hatchery-origin juveniles or 1.42 million ( 1.03 million in 2022), while 67169 ( 70603 in 2022) wild juveniles, 13212 (14 656 in 2022) wild adults and 4213 (5 198 in 2022) hatchery adults were also marked.

A recommendation has been developed by the Working Group for more efficient identification of the origin of PIT tagged salmon. The creation of a database listing individual PIT tag numbers or codes identifying the origin, source or programme of the tags should be implemented on a North Atlantic basin-wide scale. This is needed to facilitate identification of individual tagged fish, taken in marine fisheries or surveys, back to the source. Such a database has been designed by Missing Salmon Alliance UK (MSA) and IMR in Norway, and hosted and maintained by Missing Salmon Alliance (https://shiny.missingsalmonalliance.org/tag-database/). The database provides a central, searchable tag data repository against which unknown PIT detections can be searched. It also holds information on tag detections from pelagic marine fish species in the eastern Atlantic region with a network of over 20 PIT detector stations operated at fish processing plants in several countries.

Since 2003, the Working Group has reported information on marks being applied to farmed salmon to facilitate tracing the origin of farmed salmon captured in the wild in the case of escape events. In the USA, genetic "marking" procedures have been adopted where broodstock are genetically screened, and the resulting database is used to match genotyped escaped farmed salmon to a specific parental mating pair and subsequent hatchery of origin, stocking group, and marine site the individual escaped from. This has also been applied in Iceland, where in recent years, 20 out of 24 farmed escapees could be traced to the pens they escaped from by matching their genotypes to known parental genotypes, and a further three could be traced to foreign broodstocks.

Issues pertinent to particular Commission areas are included in subsequent sections and, where appropriate, carried forward to the recommendations (Annex 7).

Table 2.1.1.1. Total reported nominal catch of salmon by country (in tonnes round fresh weight), 1960-2022 (2022 figures include provisional data).

Table 2.1.1.2. Total reported nominal catch of salmon in homewaters by country (in tonnes round fresh weight), 1960-2022 (2022 figures include provisional data). S = Salmon (2SW or MSW fish); G = Grilse (1SW fish); Sm = small; Lg = large; $\mathrm{T}=$ total $=\mathrm{S}+\mathrm{G}$ or $\mathrm{Lg}+\mathrm{Sm}$.

| 1. Includes estimates of some local sales, and, prior to 1984, bycatch. |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 2. Before 1966, sea trout and sea char included (5\% of total). |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 3. Figures from 1991 to 2000 do not include catches taken in the recreational (rod) fishery. |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 4. Catch on River Foyle allocated 50\% Ireland and 50\% UK (NI). |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 5. Improved reporting of rod catches in 1994 and data derived from carcase tagging and logbooks from 2002. |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 6. Angling catch (derived from carcase tagging and logbooks) first included in 2002. |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |

7. Data extracted from NASCO website at https://nasco.int/conservation/third-reporting-cycle-2/.

Table 2.1.1.3. Available time-series of nominal catch (tonnes round fresh weight) and percentages of total catches taken in coastal, estuarine and in-river fisheries by country, 1996 to 2022. The way in which the nominal catch is partitioned among categories varies between countries, particularly for estuarine and coastal fisheries, see text for details.

| Country | Year | Coastal |  | Estuarine |  | In-river |  | Total <br> Weight (t) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Weight (t) | \% of total | Weight (t) | \% of total | Weight (t) | \% of total |  |

1. An illegal net fishery operated from 1995 to 1998, catch unknown in the first 3 years but thought to be increasing. Fishery ceased in 1999. 2001/2 catches from the illegal coastal net fishery in Lower Normandy are unknown.
2. Rod catch data for river (rod) fisheries in UK (NI) from 2002.
3. Estuarine catch included in coastal catch.
4. Coastal catch included in estuarine catch.
5. Spain catch to 2018 was Asturias catch raised, 2019 data for All Spain.
6. Iceland total catch includes ranched fish.
7. Data extracted from NASCO website at https://nasco.int/conservation/third-reporting-cycle-2/.

Table 2.1.2.1. Numbers of fish caught and released in rod fisheries along with the \% of the total rod catch (released + retained) for countries in the North Atlantic where records are available, 1991-2022. Figures for 2022 are provisional.

1. Since 2009 data are either unavailable or incomplete, however catch and release is understood to have remained at similar high levels as before.
2. Data for 2006-2009, 2014 are for the Department of Culture, Arts and Leisure area only; the figures from 2010 are a total for UK (NI). Data for 2015,2016 and 2017 are for R. Bush only.
3. The statistics were collected on a voluntary basis, the numbers reported must be viewed as a minimum.
4. Released fish in the kelt fishery of New Brunswick are not included in the totals for Canada.
5. Data extracted from NASCO website at https://nasco.int/conservation/third-reporting-cycle-2/.

Table 2.1.3.1. Estimates of unreported catches by various methods in tonnes within national EEZs in the Northeast Atlantic, North American and West Greenland Commissions of NASCO, 1987-2022.

| Year | Northeast Atlantic | North America | West Greenland | Total |

Figure 2.1.1.1. (a) Total reported nominal catches of salmon (tonnes round fresh weight) in four North Atlantic regions, 1960-2022.

Figure 2.1.1.1. (b) Total reported nominal catches of salmon (tonnes round fresh weight) in four North Atlantic regions, 1997-2022.

Figure 2.1.1.2. Nominal catch (tonnes round fresh weight) taken in coastal, estuarine and in-river fisheries by country, 2009-2022. The way in which the nominal catch is partitioned among categories varies between countries, particularly for estuarine and coastal fisheries, see text for details. Note also that the $y$-axes scales vary.

Figure 2.1.1.3. Top panel - Nominal catches (tonnes round fresh weight) taken in coastal, estuarine and in-river fisheries for the NAC area (2009-2022) and for NEAC Northern (NEAC_N) and Southern (NEAC_S) areas (20092022). Bottom panel - percentages of nominal catch taken in coastal, estuarine and in-river fisheries in each commission area, 2009-2022. Note that y -axes in the top panel vary.

Figure 2.1.3.1. Nominal North Atlantic salmon catch (tonnes round fresh weight) and unreported catch (tonnes round fresh weight) in NASCO Areas, 1987-2022.

Figure 2.2.1.1. Worldwide farmed Atlantic salmon production (tonnes round fresh weight) 1980-2022. Note no data available for USA West coast production at time of writing.

Figure 2.2.2.1. Harvest of ranched salmon (tonnes round fresh weight) in the North Atlantic, 1980-2022.

A

B

Figure 2.4.1. Location of rivers (coloured by region) with marine return rate data for wild (panel A) and hatchery origin (panel B) Atlantic salmon from the North Atlantic. Data are compiled from ICES (2021a).

Figure 2.4.2. Time series of return rates by river (coloured by region) for origin (wild, hatchery, both wild and hatchery) of smolt-to-adult returns of Atlantic salmon from the North Atlantic. Data are compiled from ICES (2021a).

Figure 2.4.3. Figure drawn from data in ICES (2019a) of returns by age group by region.

Figure 2.4.4. Contrast in return rates (\%) of all first time spawning ages groups of wild and hatchery-origin Atlantic salmon for 1SW and MSW sea age types in regions of North America (NAC), Southern NEAC (S-NEAC) and Northern NEAC ( $N$-NEAC), all years combined. The horizontal lines in each panel represent the median value over all regions for 1SW and MSW populations, respectively. Data are updated from ICES (2021a) to the 2020 smolt migration year and exclude River Oir (France).

Figure 2.4.5. Contrast in return rates (\%) by first time spawning ages (to_1SW, to_MSW, Cohort) of wild Atlantic salmon by river-specific sea age type (1SW, MSW) for rivers in North America (NAC), Southern NEAC (S-NEAC) and Northern NEAC (N-NEAC) rivers, all years combined. The horizontal lines in each panel represent the median value over all rivers for 1SW and MSW populations, respectively. Data are updated from ICES (2021a) to the 2020 smolt migration year and exclude River Oir (France).

Figure 2.4.6. Annual mean return rates of wild Atlantic salmon by river sea age type (columns) and to 1SW, MSW and for the cohort in six regions of NAC. The annual means ( $95 \%$ confidence interval error bars) are derived from a general linear model (logit transformation) with year and river within region as factors. In the case of the USA and Newfoundland MSW type river, there is only one river in the region and the values shown are the annual point estimates. A Loess smoother (span $=0.9$ ) is shown in each panel for illustration.

Figure 2.4.7. Annual mean return rates of wild Atlantic salmon by river sea age type (columns) and to 1SW, MSW and for the cohort in seven regions of NEAC. The annual means ( $95 \%$ confidence interval error bars) are derived from a general linear model (logit transformation) with year and river within region as factors. In the case of Iceland, Ireland, UK (Northern Ireland) and UK (Scotland), there is only one river in the region and the values shown are the annual point estimates. A Loess smoother (span $=0.9$ ) is shown in each panel for illustration.

Figure 2.4.8. River-specific trends in return rates of wild Atlantic salmon to monitored rivers of NAC. The rivers are aligned generally south to north by row. A Loess smoother ( $s p a n=0.9$ ) is shown in each panel for illustration.

Figure 2.4.9. River-specific trends in return rates of wild Atlantic salmon to monitored rivers of NEAC. The rivers are aligned top to bottom from Iceland, France and north to Norway. A Loess smoother (span $=0.9$ ) is shown in each panel for illustration.

Figure 2.4.10. Examples of trends in returns rates of wild Atlantic salmon smolts and hatchery origin smolts to monitored rivers in the North Atlantic as reported in ICES (2021a).

Figure 2.5.1.1. Map of telemetry study area showing study rivers, tag release sites and major receiver arrays. Cascapédia River = 1, Restigouche River = 2, Northwest Miramichi = 3, Little Southwest Miramichi = 4, and Southwest Miramichi = 5 .

Figure 2.5.1.2. Probability of cumulative smolt survival from four index rivers for the head of tide (HoT), Outer bay and the Gulf of St Lawrence to the exit at the Strait of Belle Isle (SoBI), 2003-2022. Estimates have been standardized for a smolt mean fork length of 14.5 cm .

Figure 2.5.2.1. Map of the "Atlantic salmon in the Eastern Canadian offshore regions (ESRF Regions 8 to 15): timing, duration and the effects of environmental variability and climate change" study area. Yellow mark indicate the location of acoustic receivers deployed by project partners, the tracks of the wave glider missions and drifters. The ESRF Regions 8 to 15, the focus area of the study, are highlighted by the shaded polygon.

Figure 2.5.5.1. Pop-off location of all PSAT tags released at West Greenland from 2018-2022 by continent of origin. A number of tags released in 2022 may still be active and additional tagging is planned for 2023. Two pop-off locations occur east of the map scale, but projection issues prevented them from being displayed on this map.

## 3 Northeast Atlantic Commission area

### 3.1 NASCO has requested ICES to describe the key events of the $\mathbf{2 0 2 1}$ and $\mathbf{2 0 2 2}$ fisheries

### 3.1.1 Fishing at Faroe Islands

No fishery for salmon has been prosecuted since 2000.

### 3.1.2 Key events in NEAC homewater fisheries

In 2021, ICES advised that there were no mixed-stock fisheries options on the NEAC stock complexes at the Faroes for the fishing seasons 2021/2022 to 2023/2024 (ICES, 2021). NASCO subsequently agreed a multiannual (three-year) decision for the Faroes fishery stipulating not to set a quota for these seasons. The measure for 2022/2023 and 2023/2024 was predicated on the application of a Framework of Indicators (FWI) to provide an annual check that there had been no substantive change in the forecasts of abundance. The FWI was not applied in January 2022 as originally planned. However, when the FWI was applied in January 2023, there was no indication that the forecast estimates of abundance for the four NEAC stock complexes in the FWI had been underestimated. There was, therefore, no need for a full reassessment by ICES in 2023.

Norway: The total number of marine fishers actively fishing was 431 in 2021 and 351 in 2022, a notable marked reduction from 2020 ( 956 marine fishers). The reason for this reduction are changes of the rules for marine fishing for Atlantic salmon from 2021. In 2021, bagnet fishing was banned in coastal areas south of Finnmark. This led to bagnet fishing only being permitted in selected fjords from Troms to Rogaland (the part of Norway facing westwards), and no bagnet fishing at all in the southeastern part of Norway (Agder to the border with Sweden). In Finnmark (the northernmost part of Norway), bagnet and bend-net fishing were banned in the Tana-fjord and adjacent coastal areas, because of the state of the Tana salmon stock. In 2022, bend-net fishing was banned also in Finnmark, leading to this gear no longer being legal to use in Norway. For bagnets the regulations from 2021 was continued in 2022, with minor exceptions.

River Teno/Tana (Finland/Norway): Because of the poor status of salmon populations in the River Teno/Tana (Finland/Norway) in recent years, a total salmon fishing moratorium was implemented for both 2021 and 2022. The salmon fishing ban was also extended to the Tanafjord and nearby Barents Sea coast in Norway.
In addition, any significant impacts of the COVID-19 pandemic on salmon fisheries in NEAC countries in 2021 are summarized in Section 2.3.1. However, such reported impacts were much less extensive than 2020.

### 3.1.3 Gear and effort

No notable changes in gear type used were reported in 2021 and 2022 (except for the cessation of bend-net fisheries in Finnmark, Norway in 2022), however, changes in effort were recorded. The number of gear units licensed or authorized in several of the NEAC area countries provides a partial measure of effort (Table 3.1.3.1), but does not take into account other restrictions, for example, closed seasons. In addition, there is no indication from these data of the actual number of licences actively utilized or the time each licensee fished.

The numbers of gear units used to take salmon with nets and traps have declined markedly over the available time-series in all NEAC countries. This reflects the closure of many fisheries and increasingly restrictive measures to reduce levels of exploitation in many countries. There are fewer measures of effort in respect of in-river rod fisheries, and these indicate differing patterns over available time-series. However, anglers in all countries are increasingly practicing catch and release (see below).

Trends in effort are shown in Figures 3.1.3.1 and 3.1.3.2 for the Northern and Southern NEAC countries respectively. In the Northern NEAC area, the number of bagnets and bend-nets in Norway has decreased for the past 15-20 years and in 2021 and 2022, the numbers were substantially reduced from 2020, and the use of bend-nets was phased out in 2022. No effort information is available from Russia since 2020.

The numbers of gear units licensed in UK (England and Wales) and Ireland (Table 3.1.3.1) in 2021-2022 were among the lowest reported in the time-series. In UK (England and Wales), licences were only issued for sea trout fishing and therefore no net fishing for salmon has taken place following the introduction of the National Salmon and Sea Trout Protection byelaws in 2019 in UK (England) with additional restrictions introduced in UK (Wales) in 2020. In UK (Scotland) the numbers of fixed engines, and net and cobles have been among the lowest in the timeseries in 2021-2022. For UK (Northern Ireland) driftnet, draft-net, bagnets and boxes decreased throughout the time-series and no commercial fishing activity has occurred in coastal Northern Irish waters since 2012. In France, the number of nets in estuaries and in freshwater have slightly decreased during the latest years. No data for 2021-2022 from freshwater nets were available for France at the time of the Working Group meeting.

Rod effort trends, where available, have varied for different areas across the time-series (Table 3.1.3.1). In the Northern NEAC area, the number of anglers and fishing days in the River Teno/Tana showed a dramatic decrease in 2017 following a new fishery agreement between Finland and Norway, and all salmon fishing has been closed in 2021-2022. The number of anglers has stayed relatively stable at the River Näätämöjoki in Finland. In the Southern NEAC area, rod licence numbers have decreased in UK (England and Wales), and 2022 showed the lowest figure in the time series. In Ireland, there has been an increase in the numbers of licences issued since 2020. In France, the rod-and-line effort in freshwater has been relatively stable over the latest years, although the figure in 2022 was below long-term averages.

### 3.1.4 Catches

NEAC area catches are presented in Table 3.1.4.1. The nominal catch in the NEAC area in 2021 ( 491 t ) was lower than the updated catch for $2020(768 \mathrm{t}$ ) and $38 \%$ and $47 \%$ below the previous five-year (inclusive) and ten-year (inclusive) means, respectively. Provisional nominal catch estimates for $2022(568 \mathrm{t})$ indicate that this figure has increased compared to 2021 but is still $28 \%$ and $39 \%$ below the previous five-year and ten-year means respectively. It should be noted that changes in nominal catch may reflect changes in exploitation rates and the extent of catch and release in rivers, in addition to stock size, and thus cannot be regarded as a direct indicator of abundance.

Both the total nominal catch in Northern NEAC in 2021 ( 419 t ) and provisional total nominal catch in 2022 ( 510 t ) were lower than the updated catch for $2020(689 \mathrm{t})$ and the previous fiveyear and ten-year means ( $689 \mathrm{t}, 760 \mathrm{t}$, respectively). In the Southern NEAC area, the total nominal catch for $2021(72 \mathrm{t})$ and the provisional total nominal catch in $2022(58 \mathrm{t})$ were lower than the updated catch for $2020(79 \mathrm{t})$ and below the previous five-year (100 t) and ten-year (172t) means respectively (both means inclusive of 2021). The greatest reductions in catches in Southern NEAC since 2018 were observed in UK (England and Wales) where the catch in 2019 ( 5 t ) was only $12 \%$
of the catch in $2018(42 \mathrm{t})$, and the 2020 catch was even lower ( 3 t ). The reduction is largely a result of closure of all net fisheries targeting salmon in this area.

Figure 3.1.4.1 shows the trends in nominal catches of salmon in the Southern and Northern NEAC areas from 1971 to 2022. The catch in the Southern NEAC area has declined over the period from about 4500 t in 1972 to 1975 to below 1000 t since 2003 . The catch fell sharply in 1976, and between 1989 and 1991, and has steadily decreased by an order of magnitude over the last 20 years, from over 1000 t in 2002 to currently below 100 t . The catch in the Northern NEAC area declined over the time-series, although this decrease was less distinct than the reductions noted in the Southern NEAC area. The catch in the Northern NEAC area varied between 2000 t and 2800 t from 1971 to 1988, fell to a low of 962 t in 1997, and then increased to over 1600 t in 2001. Catch in the Northern NEAC area has exhibited a downward trend since and has been consistently below 1000 t since 2012. Thus, the catch in the Southern NEAC area, which comprised around $2 / 3$ of the total NEAC catch in the early 1970s, has been lower than that in the Northern NEAC area since 1999, and has been around $1 / 5$ of the total catch in the NEAC area in recent years.

### 3.1.5 Catch per unit of effort (CPUE)

CPUE can be influenced by various factors, such as fishing conditions, perceived likelihood of success and experience. Both CPUE of net and rod fisheries might be affected by measures taken to reduce fishing effort, for example, changes in regulations affecting gear. If changes in one or more factors occur, a pattern in CPUE may not be immediately evident, particularly over larger areas. It is, however, expected that for a relatively stable effort, CPUE can reflect changes in the status of stocks and stock size. CPUE may be affected by increasing rates of catch and release in rod fisheries.

The CPUE data are presented in Tables 3.1.5.1 to 3.1.5.6. The CPUE for rod fisheries have been derived by relating the catch to rod days or angler season. CPUE for net fisheries were calculated as catch per licence-day, gear-day, licence-tide, trap-month or crew-month.

In the latest years, several CPUE data time-series have been discontinued because of fishery regulations or information being otherwise not available (Tables 3.1.5.1. to 3.1.5.6). Therefore, the Figure 3.1.5.1 shows long-term trends for only eight CPUE datasets in contrast to the 18 trends that were earlier presented from various fisheries in the NEAC area.

In the Northern NEAC area, a general increasing trend was observed for the CPUE in the Norwegian net fisheries (Figure 3.1.5.1). In Finland, the CPUE per angler-season in 2021-2022 has been estimated only for the river Näätämöjoki because of the recent salmon fishery moratorium at the River Teno. The CPUE of the Näätämöjoki rod fishing has been relatively stable over time (Figure 3.1.5.1).

In the Southern NEAC area, UK (England and Wales) measures introduced under the Salmon and Sea Trout Byelaws since 2019 required the closure of several net fisheries and mandatory $C \& R$ in others, and therefore, CPUE figures have not been calculated for 2019-2022 (Table 3.1.5.3). The CPUE for the net and coble fisheries in UK (Scotland) show a general decline over the time-series (Figure 3.1.5.1). Another time-series in UK (Scotland) for CPUE has been available from the fixed engine fisheries, but in recent years data exclude both reported catch and effort from the Solway region and therefore CPUE estimates are not available since 2016. (Table 3.1.5.5). The CPUE values for rod fisheries in UK (England and Wales) show a general positive trend (Figure 3.1.5.1) and an increase in 2022 from the previous year (Table 3.1.5.4). In France, the CPUE for rod fisheries shows an overall decline over the time series (Figure 3.1.5.1), and the 2022 figure was slightly lower than in the previous year and the long-term means (Table 3.1.5.1).

### 3.1.6 Age composition of catches

The percentage of 1SW salmon in NEAC catches is presented by country in Table 3.1.6.1 and shown separately for Northern and Southern NEAC countries in Figure 3.1.6.1. Except for Iceland, the percentage of 1SW salmon has declined for all countries over the period 1987-2022, especially so for Sweden and Spain. The decline in the percentage of 1SW salmon is evident in both stock complexes, particularly after 2000 (Figure 3.1.6.1). The overall percentage of 1SW fish in Northern NEAC catches remained reasonably consistent in the period 1987-2000 (mean 66\%, range $63 \%$ to $71 \%$ ), but has fallen in more recent decades (2001-2022) to $60 \%$ (range $53 \%$ to $68 \%$ ), when greater variability among countries and years has also been evident. Comparing the two periods, the percentage of 1SW fish has decreased in Russia, Norway, Finland, and Sweden, whereas an increase is apparent for Iceland. On average, 1SW fish comprise a higher percentage of the catch in Iceland than in the other Northern NEAC countries in the period 2001-2022 (Table 3.1.6.1), this may be related to increased catch and release of MSW fish in Iceland. In the Southern NEAC area, the percentage of 1SW fish in catches averaged $61 \%$ (range $49 \%$ to $67 \%$ ) in 19872000 and $54 \%$ (range $44 \%$ to $66 \%$ ) in 2001-2022. Comparing the two periods, the percentage of 1SW salmon has decreased in all Southern NEAC countries presented (Table 3.1.6.1), especially so for Spain.

### 3.1.7 Farmed and ranched salmon in catches

The contribution of farmed and ranched salmon to national catches in the NEAC area in 2021 and 2022 was again generally low in most countries. Farmed and ranched fish are included in assessments of the status of national stocks (Section 3.3) for Norway.

The number of farmed salmon that escaped from Norwegian farms in 2021 and 2022 was reported to be approximately 67000 fish and 56000 fish (provisional figure) respectively.). Both numbers are well below the average of the previous ten years (141 000 fish). An assessment of the likely effect of these fish on the estimates of PFA has been reported previously (ICES, 2001).

The estimated proportion of farmed salmon in Norwegian angling catches in 2021 and 2022 were the lowest in the time-series ( $1 \%$ in both years), and the proportion in samples taken from Norwegian rivers in autumn in both 2021 and 2022 (4\%), were also among the lowest values in the time-series. No data are available for the proportion of farmed salmon in coastal fisheries in Norway. A small number of escaped farmed salmon was also reported from catches in Icelandic rivers in 2021 (five individuals) and 2022 ( 32 individuals). A small proportion of the catch in UK (Scotland) ( $0.23 \%$ of retained, 0.02 of all catch including catch and released salmon) in 2022 were reported to be of farmed origin.
The release of smolts for commercial ranching purposes ceased in Iceland in 1998 but ranching for rod fisheries in two Icelandic rivers continued in 2021 and 2022. Icelandic catches have traditionally been split into two separate categories, wild and ranched (Table 2.2.2.1). In 2021, 15 t of catch were reported as ranched salmon in contrast to 32 t harvested as wild. In 2022, 21 t of catch were reported as ranched salmon in contrast to 29 t harvested as wild. Similarly, Swedish catches have been split into two separate categories, wild and ranched (Table 2.2.2.1). In 2021, 7 t of catch were reported as ranched salmon in contrast to $4 t$ harvested as wild. In 2022, 4 t of catch were reported as ranched salmon in contrast to 4 t harvested as wild. Ranching occurs on a much smaller scale in Ireland and UK (Northern Ireland).

### 3.1.8 National origin of catches

### 3.1.8.1 Catches of Russian salmon in northern Norway

The Working Group has previously reported on catches of Russian salmon in northern Norway based on results from the Kolarctic Salmon project (Kolarctic ENPI CBC programme 2007-2013) (ICES, 2020). No new information was presented to the Group in 2021.

There was no meeting in 2022 of the Working Group on Atlantic salmon in Finnmark County and the Murmansk Region, established under the Memorandum of Understanding between the Ministry of Climate and Environment (Norway) and the Federal Agency for Fishery (the Russian Federation).

In 2020 the Kolarctic ENI CBC project CoASal "Conserving our Atlantic salmon as a sustainable resource for people in the North; fisheries and conservation in the context of growing threats and a changing environment (KO4178)" was started. The project aimed to document and examine the effect of new coastal salmon fishery regulations, study the effects of growing threats Atlantic salmon populations face today with climate change, growing cage culture industry and emerging diseases. Project partners were from Norway: the County Governor of Troms and Finnmark (Lead Partner) and Institute of Marine Research, from Russia: Polar branch of VNIRO (PINRO), from Finland: University of Turku, Biodiversity Unit and from Sweden: Swedish University of Agricultural Sciences. The project was conducted in the period from January 2020 to January 2023. The project was funded through EU's Kolarctic ENI CBC programme, national funding and funding from the partners. The project followed up and built on the results from the "Kolarctic salmon (KO197)" project (2011-2013).

Results from the project have been provisionally reported at a website hosted by the county governor of Troms and Finnmark (https://www.statsforvalteren.no/nb/troms-finnmark/miljo-klima/internasjonalt-samarbeid/atlantisk-laks-i-barentsregionen--atlantic-salmon-in-the-bar-ents-region/(). In these reports, the contribution of Russian populations to the coastal fishery in northern Norway is reported and compared to earlier results from the Kolarctic salmon project.

Due to the conflict in Ukraine, Russia's participation in the project was suspended, and no new data or samples were received from Russia.

### 3.1.9 Exploitation indices of NEAC stocks

Exploitation rates for 1SW and MSW salmon from the Northern NEAC (1983 to 2022) and Southern NEAC (1994 to 2022) areas are displayed in Figure 3.1.9.1. National exploitation rates are an output of the NEAC PFA Run Reconstruction model. These were combined as appropriate by weighting each individual country's exploitation rate to the reconstructed returns.

The exploitation rates for 1SW salmon in both Northern NEAC and Southern NEAC areas have shown a general decline over the time-series (Figure 3.1.9.1). There was a notable sharp decline in 2007, as a result of the closure of the Irish driftnet fisheries in the Southern NEAC area, and in 2021 in the Northern NEAC area, in Norway, because of the reduction in effort in the bagnet fisheries as well as the likely influence of the presence of large numbers in pink salmon in the northernmost part of the country. In addition, the cessation of bend-net fisheries in Norway in 2022 also influenced the decline in overall exploitation for Northern NEAC areas. The weighted exploitation rate on 1SW salmon in the Northern NEAC area was $31 \%$ in 2021 and $34 \%$ in 2022, which was lower than the previous five-year ( $43 \%$ ) and ten-year ( $41 \%$ ) means. Exploitation on 1SW fish in the Southern NEAC complex was $7 \%$ in 2021 and 2022, which was at the same level as the previous five-year mean ( $8 \%$ ) but lower than the previous ten-year mean ( $10 \%$ ).

The exploitation rate of MSW fish also exhibited an overall decline over the time-series in both Northern NEAC and Southern NEAC areas (Figure 3.1.9.1), with a notable sharp decline in 2008 and 2021 in Northern NEAC. Exploitation on MSW salmon in the Northern NEAC area was $35 \%$ in 2021 and 2022, which was lower than the previous five-year mean ( $44 \%$ ) and the ten-year mean (44\%). Exploitation on MSW fish in Southern NEAC was 3\% in 2021 and 2022, which was lower than the previous five-year (5\%) and ten-year (6\%) means.
The rate of change of exploitation of 1SW and MSW salmon in NEAC countries over the time periods 1983 to 2022 for Northern NEAC and 1994 to 2022 for Southern NEAC is shown in Figure 3.1.9.2. This was derived from the slope of the linear regression between time and natural logarithm transformed exploitation rate. The relative rate of change of exploitation over the entire time-series indicates an overall reduction of exploitation in most Northern NEAC countries for 1SW and MSW salmon (Figure 3.1.9.2). The greatest rate of decrease in Northern countries was shown for MSW fish in Iceland (Northeast) and 1SW fish in Russia, while lowest rate of decrease was shown for MSW fish in Russia during the time-series. The Southern NEAC countries have also shown a general decrease in exploitation rate (Figure 3.1.9.2) on both 1SW and MSW components, except for 1SW salmon in France where exploitation for 1SW salmon has increased over the time-series. The greatest rate of decrease was shown in UK (England and Wales and Northern Ireland), while France (MSW) and Iceland (both 1SW and MSW) showed relative stability in exploitation rates during the time-series.

### 3.2 Management objectives and reference points

### 3.2.1 NEAC conservation limits

River-specific Conservation Limits (CLs) have been derived for salmon stocks in most countries in the NEAC area (France, Ireland, UK (England and Wales), UK (Northern Ireland), UK (Scotland), Finland, Norway and Sweden) and these are used in national assessments. In these cases, CL estimates for individual rivers are summed to provide estimates at the national level for these countries.

River-specific CLs have also been derived for a number of rivers in Russia and Iceland, but these are not yet used in national assessments. An interim approach has been developed for countries that do not use river-specific CLs in their national assessment. This approach is based on the establishment of pseudo-stock-recruitment relationships for national salmon stocks; further details are provided in the Stock Annex (Annex 5).

CL estimates for all individual countries are summed to provide estimates for the Northern and Southern NEAC stock complexes (Table 3.2.1.1). These data are also used to estimate the Spawner Escapement Reserves (SERs; the CL increased to take account of natural mortality between the recruitment date of 1st January in the first sea winter and return to home waters). SERs are estimated for maturing and non-maturing 1SW salmon from individual countries as well as the Northern NEAC and Southern NEAC stock complexes (Table 3.2.1.1). The Working Group considers that the current national CL and SER levels may be less appropriate for evaluating the historical status of stocks (e.g. pre-1985), which in many cases have been estimated with less precision.

### 3.2.2 Progress with setting river-specific conservation limits

### 3.2.2.1 France

A management-oriented research project (Rénovation de la stratégie de gestion du saumon en Bretagne, RENOSAUM) was undertaken to lay the foundation to revise the rationale of CL setting in Brittany (France) using three decades (1987-2020) of data for 18 salmon rivers. During the project, hierarchical models were built to: (i) estimate the numbers of adult returns and young-of-the-year (YOY) recruitment, (ii) model the exploitation regime of Atlantic salmon by the recreational fishery, and (iii) the generation renewal process for each river.

The new CL definition is based on the premise that conservation should aim at avoiding, i.e. controlling the risk of low recruitment. The CL is set at the egg deposition equivalent to a risk of $25 \%$ of producing less than half of the carrying capacity. The CL values are derived from riverspecific stock-recruitment (SR) relationships, relating the number of eggs produced by prespawning females (stock) to the abundance of the resulting young-of-the-year juveniles (recruitment). A hierarchical SR model, based on a Beverton-Holt type relationship with a mixture of lognormal process errors, was used for the joint analysis of all populations. Relying on the Bayesian framework for statistical inference, the risk associated to the CLs fully integrates the major sources of uncertainty, which are recruitment stochasticity, measurement errors of the stock and recruitment, and estimation of the SR relationship.

Compared to the previous CLs based on MSY, the new CL values are higher for rivers of low productivity, which means that salmon fisheries management is more cautious for these rivers than before. The new CLs have been implemented for the 18 salmon rivers in Brittany from 2019, and they will be used to assess CL compliance on river-by-river basis and to update the national CL.

### 3.2.2.2 Finland/Norway

A CL was set for the River Näätämöjoki/Neidenelva, which is a transboundary river that crosses northern Finland and Norway. The CL was estimated as a spawning target following the Norwegian methodology (Forseth et al., 2013). Based on the stock-recruitment relationship, the female biomass necessary to attain carrying capacity (yielding average maximum recruitment) was established as a CL for the population. Data compilation and preparations to undertake a CL compliance assessment for the stock are underway in collaboration between Finnish and Norwegian experts.

### 3.3 Status of stocks

### 3.3.1 The NEAC PFA run-reconstruction model

The Working Group uses a run-reconstruction model to estimate the PFA of salmon from countries in the NEAC area (Potter et al., 2004). PFA in the NEAC area is defined as the number of 1SW recruits on 1 January in their first winter at sea. The model is generally based on the annual retained catches in numbers of 1SW and MSW salmon in each country, which are raised to take account of minimum and maximum estimates of non-reported catches and exploitation rates of these two sea age groups. These values are then raised further to take account of the natural mortality between 1 January in the first sea winter and the mid-date of return of the stocks to freshwater.

Where the standard input data are themselves derived from other data sources, the raw data may be included in the model to permit the uncertainty in these analyses to be incorporated into
the modelling approach. Some countries have developed alternative approaches to estimate the total returning stock, and the Working Group reports these changes and the associated data inputs in the year in which they are first implemented.

For some countries, the data are provided in two or more regional blocks. In these instances, model output is provided for the regional blocks and is combined to provide stock estimates for the country as a whole. The input data for Finland comprise the total Finnish and Norwegian catches (net and rod) for the River Teno/Tana, and the Norwegian catches from this river are not included in the input data for Norway.

A Monte Carlo simulation (9999 resamples) is used to estimate confidence intervals on the stock estimates. Further details of the model are provided in the Stock Annex, including a step-by-step walkthrough of the modelling process.

### 3.3.2 Changes to the national input data for the NEAC PFA run-reconstruction model

Model inputs are described in detail in Section 2.2 of the Stock Annex. In addition to adding new data for 2021 and 2022, the following changes were made to the national/regional input data for the model:

UK (England andWales): The UK (England and Wales) run-reconstruction model input data for 2020 were updated to account for reduced angling activity due to the coronavirus (COVID-19) pandemic and associated lockdown to prevent its spread. The 2020 data were updated using a statistical model to derive expected angler rod released catch and effort from the preceding six years, as well as revisions to 1SW and MSW salmon catch proportions and exploitation rates along with their error terms.

River Teno/Tana (Finland and Norway): A salmon fishing moratorium was implemented in 2021 and hence there was no reported catch in the 2021 and 2022 fishing seasons. Data from a sonar counter, which is assumed to count $96 \%$ of all fish and can separate between 1SW and MSW salmon by length, was used to calculate the numbers of returns. The exploitation rate (illegal fishing) was assumed to be uniformly distributed between $2 \%$ and $4 \%$. To implement this in the run-reconstruction model, reported catch was set to one fish for both 1SW and MSW salmon, and the unreported catch was altered accordingly so the total returns produced by the run-reconstruction model would equal the sonar count estimate for the average exploitation rate of $3 \%$. There is currently ongoing work in Finland and Norway to make a Bayesian model for providing better estimates of the number of returns to Teno/Tana.

Ireland: Exploitation rates along with their error terms were revised for 1SW salmon in 2018 to account for reduced recreational angling due to summer drought, and for MSW salmon in 2020 and 2021 to account for reduced recreational angling due to COVID in spring of each year.

Russia: Data on catch numbers, exploitation rates and unreported catch rates were not available to the Working Group for the years 2021 and 2022 for any of the four Russian stock units. In the absence of data, exploitation rates and unreported catch rates together with their associated errors were assumed unchanged from previous years. With respect to catches, the total catch for Russia in wet mass for all stock units and sea ages combined was available for both 2021 (55.38 t) and 2022 ( 48.82 t) (NASCO, 2023). The ratios of the total catch for Russia in 2021 and 2022 to the mean total catch for the last five years of available stock unit data ( 2016 to 2020) were used to scale the mean catches by sea age and stock unit for the same five-year period to derive estimated catches for 2021 and 2022.

A variance adjustment parameter was added to the data for each Russian stock unit and sea age. This parameter captures the necessary increase in the variance in return estimates to ensure that they reflect the expected uncertainty arising from the method of estimating catches as described above. The scaling parameters were derived numerically by considering the error between the returns derived from observed catches and the returns derived from catches estimated using the above method applied to the period 2016 to 2020. Additional details on the estimation of catches in 2021 and 2022 and the adjustment to the uncertainty in the returns can be found in Annex 9.

### 3.3.3 Changes to the NEAC PFA run-reconstruction model

Russia: To accommodate the use of an estimated catch in the absence of observed data, changes were made to the run-reconstruction model to allow for the scaling of the variance in the returns to reflect the additional uncertainty expected from the catch estimation process described in section 3.3.2. Due to the increased uncertainty in the returns, and the way in which spawner abundances are derived, the distribution of spawner abundance estimates in some Russian stock units could include negative values as a result of this change. To prevent this, the distributions of spawner abundance estimates were truncated at a value of 1 . Additional details on the estimation of catches in 2021 and 2022 and the adjustment to the uncertainty in the returns can be found in Annex 9.

### 3.3.4 Description of national stocks and NEAC stock complexes as derived from the NEAC run-reconstruction model

The NEAC PFA run-reconstruction model provides an overview of the status of national salmon stocks in the Northeast Atlantic. It does not capture variations in the status of stocks in individual rivers or small groups of rivers, although this has been addressed, in part, by the regional splits within some countries and the analysis set out in Section 3.3.5.

The model output for each country has been displayed as a summary sheet (Figures 3.3.4.1(a-j)) comprising the following:

- PFA and SER of maturing 1SW and non-maturing 1SW salmon.
- Homewater returns and spawners ( $90 \%$ confidence intervals) and CLs for 1SW and MSW salmon.
- Exploitation rates of 1SW and MSW salmon in homewaters estimated from the returns and catches.
- Total catch (including unreported) of 1SW and MSW salmon.
- National pseudo stock-recruitment relationship (PFA against lagged egg deposition) is used to estimate CLs in countries (i.e. Iceland and Russia) that do not provide one based upon river-specific estimates (Section 3.2). This panel also includes the sum of the riverspecific CLs where this is used in the assessment.

Tables 3.3.4.1-3.3.4.6 summarize salmon abundance estimates for individual countries and stock complexes in the NEAC area. The PFA of maturing and non-maturing 1SW salmon and the numbers of 1SW and MSW spawners for the Northern NEAC and Southern NEAC stock complexes are shown in Figure 3.3.4.2.

The model provides an index of the current and historical status of stocks based on fisheries data. The 5th and 95th percentiles shown by the whiskers in each of the plots (Figures 3.3.4.1 and 3.3.4.2) reflect the uncertainty in the input data. It should also be noted that the results for the full time-series can change when the assessment is re-run from year to year and as the input data are refined (as such, it should be noted that the 2021 results are obtained from the 2022 analyses).

In this regard, changes to the data inputs for UK (Scotland) resulted in alterations to the PFA and spawner time-series, and changes to the data inputs for UK (Northern Ireland) and UK (Scotland) resulted in changes in their CL and SER values and those for the Southern NEAC stock complex. For 2021 and 2022, no exploitation occurred in the Teno/Tana owing to fisheries closure, and Russian estimates are derived from total reported catches provided in tonnes (NASCO, 2023) and split into the four Russian regions and the two sea age classes using a method detailed in Annex 9.

Status of stocks is assessed relative to the probability of returns exceeding CLs, or for PFA, SERs. Based on the NEAC run-reconstruction model, the status of the two age groups of the Northern NEAC stock complex, prior to the commencement of distant-water fisheries in the latest available PFA year, were considered to be at full reproductive capacity (i.e. above the SER; Section 1.5; Figure 3.3.4.2). The abundances of both maturing 1SW and non-maturing 1SW recruits (PFA) for Northern NEAC (Figure 3.3.4.2) show a general decline over the period, with the decline more marked in the maturing 1SW stock. In 2021, the numbers of maturing 1SW and non-maturing 1SW recruits (PFA) are at their lowest point since the start of the time-series. The 1SW spawners in the Northern NEAC stock complex have been at full reproductive capacity throughout the time-series with the exception of 2021. MSW spawners, on the other hand, have periodically been at risk of suffering reduced reproductive capacity, but not in the last 10 years (Figure 3.3.4.2).

The status of the two age groups of the Southern NEAC stock complex, prior to the commencement of distant-water fisheries in the latest available PFA year, were considered to be at full reproductive capacity for 1 SW non-maturing stocks and at risk of suffering reduced reproductive capacity for the 1SW maturing stocks. The status of the two age groups of Southern NEAC stock complex at spawning were considered to be at full reproductive capacity for MSW stocks and suffering reduced reproductive capacity for the 1SW stocks.

The abundances of both maturing 1SW and non-maturing 1SW recruits (PFA) show a general decline over the period (Figure 3.3.4.2). The decline was more marked in the maturing 1SW stock with five of the most recent 10 years being at risk of suffering or suffering reduced reproductive capacity (i.e. below or overlapping the SER). MSW stocks (non-maturing 1SW PFA) were considered to be at full reproductive capacity prior to the commencement of distant-water fisheries in the latest available PFA year (Figure 3.3.4.2). The 1SW spawners in the Southern NEAC stock complex have been mainly at full reproductive capacity throughout the time-series, but in eight of the ten last years have been at risk of suffering or suffering reduced reproductive capacity. In contrast, MSW spawners have been at risk of suffering reduced reproductive capacity or suffering reduced reproductive capacity for most of the time-series, although they have been at full reproductive capacity for all of the most recent ten years (Figure 3.3.4.2).

### 3.3.4.1 Individual country stocks

The assessment of PFA against SER (Figure 3.3.4.3a-b) and returns and spawners against CL are shown for individual countries (Figures 3.3.4.4a-b and 3.3.4.5a-b) and by regional blocks (Figures 3.3.4.6a-b and 3.3.4.7a-b) for the most recent PFA and for 2021 (a) and 2022 (b) return years. These assessments show the same broad contrasts between Northern and Southern NEAC stocks as was apparent in the stock complex data.

For all countries in Northern NEAC, the PFAs of both maturing and non-maturing 1SW stocks were at full reproductive capacity prior to the commencement of distant-water fisheries in the most recent PFA years, except for maturing and non-maturing 1SW stocks in the Tana/Teno (Finland and Norway) and 1SW maturing stocks in Russia, which were at risk of suffering or suffering reduced reproductive capacity (Figure 3.3.4.3 a-b). Note that for 2021 and 2022, values for Russia are derived from total reported catches provided in tonnes (NASCO, 2023) and should be taken with caution. Returning and spawning 1SW and MSW stocks in Sweden and Norway as
well as 1SW returning stocks in Iceland were at full reproductive capacity in 2021 and 2022. However, both 1SW and MSW returns and spawner stocks in the River Teno/Tana (Finland and Norway) and in Russia were at risk of suffering or suffering reduced reproductive capacity, except for MSW returns in Russia (which are based on data derived from reported catches in NASCO, 2023) which were at full reproductive capacity (Figures 3.3.4.4 a-b and 3.3.4.5 a-b). In addition, 1 SW and MSW spawners in Iceland were at risk of suffering or suffering reduced reproductive capacity in 2021 and 2022 (Figures 3.3.4.4 a-b and 3.3.4.5 a-b).
In Southern NEAC, maturing and non-maturing stocks in UK (Northern Ireland), Ireland and France were suffering or at risk of suffering reduced reproductive capacity both prior to the commencement of distant-water fisheries and at spawning (Figures 3.3.4.3-3.3.4.5). 1SW returns and spawners were all suffering reduced reproductive capacity in 2021 and 2022, apart from UK (Scotland). Here, maturing and non-maturing stocks were at full reproductive capacity prior to the commencement of distant water fisheries (Figure 3.3.4.3a-b), and for returns and spawners (Figures 3.3.4.4a-b-3.3.4.5a-b) with the sole exception of MSW spawners in 2021 which were at risk of suffering reduced reproductive capacity (Figure 3.4.4.5a). In addition, in UK (England and Wales), the 1SW maturing stock was suffering reduced reproductive capacity both prior to the commencement of distant water fisheries and at spawning in 2021 and 2022 (Figure 3.3.4.3a-b), whereas the non-maturing 1SW stock and MSW returns and spawners were at full reproductive capacity for both years (Figures 3.3.4.4a-b-3.3.4.5a-b).

Figures 3.3.4.6(a-b) and 3.3.4.7(a-b) provide more detailed descriptions of the status of returning and spawning stocks by country and region (where assessed) for both Northern and Southern NEAC stocks, for 2021 (a) and 2022 (b).

### 3.3.5 Compliance with river-specific conservation limits

In the NEAC area, nine jurisdictions have established river-specific CLs. Compliance with these and associated trends per jurisdiction are summarized below and presented in Figure 3.3.5.1 and Tables 3.3.5.1 and 3.3.5.2. Attainment of CLs is assessed based on spawners, after fisheries, unless otherwise indicated.

- For the River Teno (Finland/Norway), the number of major tributary stocks with established CLs rose from nine between 2007 and 2012 (with five annually assessed against CL), to 24 ( 25 including the main stem) since 2013 (with seven to 15 assessed against CL). No stocks met CL prior to 2013. A declining trend is evident in assessed stocks attaining CL from $40 \%$ in 2018 to $12 \%$ (a single stock) in 2022. The cessation of fisheries since 2021 has reduced the number of stocks available for assessment to eight as there are no catches available to inform stock size.
- CLs were established for 439 Norwegian salmon rivers in 2009, but CL attainment was retrospectively assessed for $165-170$ river stocks back to 2005 . An average of 182 stocks are assessed since 2009. A mean of $66 \%$ of river stocks have met CL over the time-series. In 2021, $71 \%$ of assessed stocks met CL, which is the lowest level of attainment since 2014. However, in 2022, $83 \%$ of assessed stocks attained CL, albeit with 20 less stocks assessed than the preceding year.
- $\quad$ Since 1999, CLs have been established for 85 river stocks in Russia (Murmansk region). In the period 1999 to 2019, eight of these have been annually assessed for CL attainment, of which $88 \%$ have consistently met their CL. However, in 2020, only two stocks were assessed with one of these meeting CL. No data are available for 2021 and 2022.
- Sweden established CLs in 2016 for 23 stocks which rose to 24 stocks since 2017. Eight of the 21 stocks assessed ( $38 \%$ ) met CL in 2016. In 2021 and 2022, $13 \%$ and $17 \%$ of assessed stocks, respectively, met CL, which is lower than the preceding mean attainment of $29 \%$.
- In France, CLs were established for 27 river stocks in 2011, rising to 37 since 2018. A mean of $5 \%$ of assessed stocks have met CL over the time-series with $3 \%$ attaining CL in 2021 and $0 \%$ in 2022. However, note that the number of rivers that met the CL corresponds to the number of rivers for which the TAC have been reached. France will review this methodology for 2024 by assessing the compliance to CL for egg deposition.
- Ireland established CLs for all 141 stocks in 2007, rising to 144 since 2020. The mean percentage of stocks meeting CLs is $36 \%$ over the time-series, with the highest attainment of $41 \%$ achieved in 2011 and 2012. In 2021 and 2022, 34\% and $33 \%$ of assessed stocks, respectively, attained CL.
- UK (England and Wales) established CLs in 1993 for 61 rivers, increasing to 64 from 1997 with an overall mean of $41 \%$ assessed stocks meeting CL over the time-series. In 2021 and 2022 , only $18 \%$ and $12 \%$, respectively, of assessed stocks met CL, the latter which is the lowest since assessments began.
- Data on UK (Northern Ireland) river-specific CLs are presented from 2002, when CLs were assigned to ten river stocks. Since 2012, 19 stocks have established CLs with up to 17 of these assessed annually for CL attainment. A mean of $41 \%$ have met their CLs over the time-series. A downward trend in CL attainment is evident from 2020 (67\%) to 2022 (13\%), with 2022 the lowest level of attainment in the time series.
- UK (Scotland) have established CLs for 173 assessment groups (rivers and small groups of rivers) with retrospective assessment conducted to 2011. For domestic management, stock status is expressed as the probability of achieving CL and attainment is set at $60 \%$. Mean attainment over the time-series was $49 \%$. In 2021, the most recent reporting year available, $32 \%$ of assessment groups met CL, a decrease of $13 \%$ on the two preceding years.

No river-specific CLs have been established for Denmark, Germany and Spain. Iceland has set provisional CLs for several salmon producing rivers representing almost half of the annual catch, and continues to work towards finalizing an assessment process for determining CL attainment.

### 3.3.6 Return rates

An overview of the trends of marine return rates for wild- and hatchery-reared smolts returning to homewaters (i.e. before homewater exploitation) is presented in Figure 3.3.6.1. The figure shows the proportional change in five-year mean return rates for smolt to 1SW (smolt years 20172021, inclusive) and smolt to 2SW (smolt years 2016-2020, inclusive) returns to rivers of Northern and Southern NEAC areas compared to their mean returns for the previous five-year period. It should be noted that: (1) Northern NEAC is represented only by the River Imsa (1SW and 2SW) in Norway, but smolt Passive Integrated Transponder (PIT)-tagging started in three rivers in Norway in 2016 and more rivers are likely to be added in future; (2) the proportional change of return rates for hatchery smolts from Southern NEAC again includes the River Bush from UK (Northern Ireland), together with Ireland and Iceland rivers; and (3) that the scale of change in some rivers is influenced by low return numbers creating high uncertainty, which might have a large consequence on the proportional change.
In Northern NEAC, the recent five-year mean return rate of wild smolts to the River Imsa (Norway) as 1 SW returns has increased compared to the previous five-year mean, from $2.85 \%$ to $3.54 \%$. In contrast, the 2 SW returns have decreased over the same period from $1.84 \%$ to $0.90 \%$. The same pattern is seen in hatchery smolts returning to the River Imsa, with 1SW hatchery returns increasing from $2.02 \%$ to $3.20 \%$ and 2 SW hatchery returns decreasing from $0.56 \%$ to $0.34 \%$.

In Southern NEAC, the pattern in five-year mean return rate of wild smolts as 1SW returns compared to the previous five-year mean was mixed, with four rivers decreasing and four rivers increasing. The largest decrease was on the Scorff (France), from $6.93 \%$ to $4.64 \%$, and the largest increase was on the Ellidaar (Iceland), from $2.33 \%$ to $4.54 \%$. The pattern in hatchery smolts returning as 1SW returns compared to the previous five-year mean was also mixed, with three rivers increasing and five rivers decreasing. Five-year mean return rates of wild smolts as 2SW returns decreased compared to the previous five-year mean in all but the Bresle (France) and the River Corrib (Ireland), although the change on the Corrib is influenced by very low return numbers and should be treated cautiously. The largest decrease in wild 2SW returns was again on the Scorff (France), from $1.34 \%$ to $0.81 \%$.

The annual return rates for different rivers and experimental facilities are presented in Tables 3.3.6.1 and 3.3.6.2. From these data, least squared (or marginal) mean annual return rates were estimated to provide indices of survival for Northern and Southern NEAC 1SW and 2SW returning adult wild and hatchery salmon groups (Figure 3.3.6.2). To account for variation due to the number of contributing experimental groups, mean annual return rates were estimated using a GLM (Generalized Linear Model) with return rates related to smolt year and river, each as factors, with a quasi-Poisson distribution (log-link function). All reported annual return rates were used to estimate the mean annual return rates, i.e. there was no restriction on the numbers of years reported, to ensure the maximum number of rivers could contribute. Note that estimated year effects are presented on a log-scaled $y$-axis.

Return rates of wild and hatchery smolts to Northern NEAC are variable (additional information is provided in Section 2.4). They have generally decreased since 1980, although rates of 1SW returns from wild smolts have stabilized since 2010, and from hatchery smolts have increased since 2005 (Figure 3.3.6.2). Rates of 2SW returns from wild and hatchery smolts to Northern NEAC are also highly variable, but have continued to decline in the most recent years, especially for wild smolts. Mean return rates of wild and hatchery smolts to Southern NEAC are less variable, primarily because they are estimated from more rivers. They too have generally decreased since 1980, although also appear to have stabilized since 2010 with an upward trend in rates of 2SW returns from wild smolts apparent since 2005.

The overall low return rates in recent years highlighted in these analyses are broadly consistent with the trends in estimated returns and spawners as derived from the PFA model (Section 3.3.4), and that abundance is strongly influenced by factors in the marine environment.

### 3.4 Advice on the risks of salmon bycatch occurring in pelagic and coastal fisheries and effectiveness and adequacy of current bycatch monitoring programmes

The following is a summary in response to ToR Question 2.4. The corresponding report is in Annex 10.

There are two main methods of analysing the risk of bycatch for salmon.
First, through the risk of exposure. This is defined as the risk of salmon being in the same place as commercial vessels with a specific gear type or targeting a particular species that is likely to intercept (catch or kill) salmon, and at a depth where the salmon would be. This approach to analysing risk requires the identification of fisheries that will have a higher risk of overlap in space and time with known salmon migration (e.g. Table 4 from the report in Annex 10). Using the matrix of fisheries with higher overlap, an exposure analysis of fishing effort from at-risk
fisheries needs to be modelled with information on the at-sea salmon probability of presence (e.g. Queiroz et al., 2019).

Second, salmon bycatch risk to stock can be analysed. ICES Working Group on Bycatch (WGBYC) developed a Bycatch Evaluation and Assessment Matrix (BEAM) which considers species abundance estimates, species variability in space, gear capture variability, and species density (Appendix 3; ICES 2022b). This method could be applied to salmon taking into consideration spatial-temporal variability at a finer resolution given their migration routes. It has, however, been reported that for species with very low detectability such as salmon the BEAM process may not be sufficiently robust.

ICES (2004) recommended that knowledge of the migration routes of salmon needed to be improved. Much progress has been made in this area (e.g. Gilbey et al., 2021; Rikardsen et al., 2021), but gaps in describing their precise migration still exist. For example, the migration routes and time spent in areas such as the North Sea, and the Barents Sea are unknown. Furthermore, although the Norwegian Sea is an important migratory pathway for post-smolt originating in southern NEAC areas, it is not known if other important migration pathways may be used for a proportion of the post-smolts. Information on adult migration is also scarce.

Equally, since the ICES Study Group on the Bycatch of Salmon in Pelagic Trawl Fisheries (SGBYSAL) undertook an analysis of pelagic fisheries bycatch of Atlantic salmon (ICES, 2004), the Working Group has reviewed pelagic and coastal fisheries bycatch risk. It should be noted that because gear and métier (including targeted fisheries) -specific fisheries data were not available at the time of writing this text, certain fisheries may have been missed. From our review, it was clear that at present salmon are caught as bycatch in coastal areas when they migrate to and from their natal rivers, but insufficient information exists on coastal fisheries to be able to evaluate coastal bycatch risk (Sumner, 2015; Elliott et al., 2023).

To understand how bycatch is being monitored and the effectiveness of that monitoring, existing national programmes and whether these programmes were efficient at detecting and reporting salmon bycatch were reviewed. Although nation-specific onboard and onshore fisheries observer programs exist, salmon bycatch monitoring appears to be more complex to appropriately record than that for larger marine mammals, birds, and reptiles (ICES, 2019b). For example:

- For pelagic fisheries few catches are monitored for bycatch, and this monitoring normally only screens a small proportion of the total catch. This is in part due to the nature of those fisheries (catching 100s of tonnes of a specific species), and in part due to the difficulties of detecting salmon among other pelagic fish in the catch (ICES, 2023b)
- At present monitoring programs focus more on demersal fisheries which are known to have high overall bycatch levels, albeit less likely to capture pelagic salmon.
- It is difficult to obtain sufficient information on the country and fishery-specific observer effort (e.g. number of observed vessel-day/total days fished, per fishery/year). In addition, this information is variable between countries but seldom exceeds $5 \%$ of a nation's total annual fishing effort (https://datacollection.jrc.ec.europa.eu/wp/2020-2021).
- There appears to be underreporting of bycatch. For example, it has been noted that salmon and diadromous fish in general, may not be reported at present through national sampling programs (Annex 10, Report Section 2.2.6.1; Charbonnel et al., 2022; 2023).
- It should also be noted that access to bycatch records and precise monitoring methods can be difficult to obtain and in numerous cases these were not available to the Working Group at the time of writing this report.

From the information collated on pelagic fisheries, a qualitative bycatch risk of exposure matrix was initiated taking into consideration certainty (Table 4 from this chapter). Too little information was available to include coastal fisheries risk of exposure to the matrix. It should also be
noted that since spatial and temporal gear and métier-specific data were not available at the time of writing the report, certain fisheries may have been missed in the matrix. From the exposure matrix, the mackerel fishery, during summer in the Norwegian Sea and south of Iceland is a high-risk fishery because of multiple levels of bycatch recorded and its overlap in space, depth, and time with migration routes and feeding areas for salmon. Furthermore, the total landings of mackerel caught in the Norwegian Sea has increased the last 10-15 years. In addition, there is a medium risk of bycatch in the fishery for herring and blue whiting in the Norwegian Sea, for herring and sandeel in the North Sea, and for capelin in the Barents Sea, horse mackerel west of the British Isles and sardine and anchovy in the Bay of Biscay.
From this review of literature on salmon bycatch the Working Group has identified the following data deficiencies, monitoring needs and research requirements:

1. Improved understanding of post-smolt and adult salmon migration route in time.
2. Move to a quantitative analysis of the risk of exposure and bycatch risk to stocks which requires access to gear and fisheries specific fishing effort data (both inshore and offshore data) at an ICES rectangle by month.
3. Include salmon on ICES WGBYC list of species and data calls. The WGBYC undertake data calls for the data required to analyse bycatch that WGNAS does not have access to. The WGBYC also undertakes similar and overlapping analysis.
4. Standardize salmon bycatch monitoring programmes across countries, including minimum effort per fishery and standards for data recording and reporting.
5. Improve at-sea and onshore observer screening, including better salmon identification guidance. Minimum data to be collected are: date, fishery, catch location, number of salmon bycatch, fork length (preferably) and/or weight. The screening of discards from factories should also be explored (recommendation from ICES, 2004) by having close collaborations with factories operators.
6. Since at present bycatch data collection is difficult to access, eDNA data collection from scientific and commercial pelagic trawls may help improve detection of salmon and improve knowledge of their migratory pathways. Uncertainty estimates from these analyses are required.

Table 3.1.3.1.a. Number of gear units licensed or authorized by country and gear type (UK (England \& Wales, Scotland, N.Ireland); Ireland; France)

## Notes:

1. Number of gear units expressed as trap months.
2. Number of gear units expressed as crew months.
3. (2022/mean -1) * 100.
4. Dash means "no data."
5. Lower Adour only since 1994 (Southwestern France), due to fishery closure in the Loire Basin
6. Adour estuary only (Southwestern France).
7. Number of fishers or boats using driftnets: overestimates the actual number of fishers targeting salmon by a factor 2 or 3.
8. Common licence for salmon and sea trout introduced in 1986, leading to a short-term increase in the number of licences issued
9. Compulsory declaration of salmon catches in freshwater from 1987 onwards.
10. Allowable effort in 2019 was zero throughout England and 1025 days were utilized in Wales

Notes:

1. All Iceland catches have been included in Northern countries
2. Since 1991, fishing carried out at the Faroes has only been for research purposes.
3. No unreported catch estimate available for Russia since 2008.
4. Estimates refer to season ending in given year.

Notes:

1. Mean of the time-series.
2. In 2022, bend-net fisheries were banned for whole of Norway.

## Notes:

1. Asturias Region only.
2. Since 1989, only three rivers are included for Russia rather than four rivers previous to this. For 2021 and 2022, values for Russia are derived from total reported catches provided in tonnes (NASCO, 2023)

Table 3.2.1.1. Conservation limit options for NEAC stock groups estimated from river-specific values, where available, or the national PFA run-reconstruction model. Spawner Escapement Reserve (SERs) based on the CLs used are also shown. All values are given in numbers of fish.

| Country and Complex | National Model CLs |  | River-specific CLs |  | Conservation Limit used |  | Spawner Escapement Reserve (SER) |  |

Notes:

1. Microtags.
2. Carlin tags, not corrected for tagging mortality.
3. Microtags, corrected for tagging mortality.
4. Assumes $50 \%$ exploitation in rod fishery.
5. From $0+$ stage in autumn.
6. Incomplete returns.
7. Assumes $30 \%$ exploitation in trap fishery.
8. France data based on returns to freshwater.
9. Bush 2SW data based on returns to freshwater
10. Time-series mean.

Notes:

1. Return rates to rod fishery with constant effort.
2. Different release sites.
3. Microtagged.
4. Time-series mean.

Figure 3.1.3.1. Overview of effort as reported for various fisheries and countries in the Northern NEAC area, 1971-2022. Notice that some of the $y$-axes are given in thousands. No data is available from Russia (Archangel region) since 2020.

Figure 3.1.3.2. Overview of effort as reported for various fisheries and countries in the Southern NEAC area, 1971-2022. Notice all the $\mathbf{y}$-axes on the right panel are given in thousands.

Figure 3.1.4.1. Nominal catches of salmon and five-year running means in the Southern and Northern NEAC areas, 19712022
$\qquad$

Norway bend-nets
Norway bag-nets
Finland rod
France rod
UK(E\&W) rod
UK(Scotl.) net \& coble

Figure 3.1.5.1. Proportional change (\%) over years in CPUE estimates in various rod and net fisheries in Northern and Southern NEAC area.

Figure 3.1.6.1. Percentage of 1SW salmon in the reported catch for the Northern (black dots) and Southern (grey dots) stock complexes, 1987-2022. Curves represent Northern (black line) and Southern (grey line) stock complexes with a Loess smoother (span $=85 \%$ ) applied to the data. For 2021 and 2022, values for Russia are derived from total reported catches provided in tonnes (NASCO, 2023)

Figure 3.1.9.1. Mean annual exploitation rate of wild 1SW and MSW salmon by fisheries in Northern and Southern NEAC countries. For 2021 and 2022, values for Russia are derived from total reported catches provided in tonnes (NASCO, 2023).

Figure 3.1.9.2. The rate of change (\%) of exploitation of 1 SW and MSW salmon in Northern NEAC (left) and Southern NEAC (right) countries. For 2021 and 2022, values for Russia are derived from total reported catches provided in tonnes (NASCO, 2023).

## R.Tana/Teno (Finland \& Norway)

Figure 3.3.4.1a. Summary of fisheries and stock description, River Teno / Tana (Finland and Norway combined). The river-specific CL, which is used for assessment purposes, is included on the national CL analysis plot (for comparison, the CL estimated from the national S-R relationship is at the inflection point). No exploitation occurred in 2021 and 2022 owing fisheries closure in the Teno/Tana.

## UK(Scotland)

Figure 3.3.4.1j. Summary of fisheries and stock description, UK (Scotland). The river-specific CL, which is used for assessment purposes, is included on the national CL analysis plot (for comparison, the CL estimated from the national $\mathrm{S}-\mathrm{R}$ relationship is at the inflection point).

Figure 3.3.4.2. Estimated PFA (left panels) and spawning escapement (right panels) with $90 \%$ confidence limits, for maturing 1SW (1SW spawners) and non-maturing 1SW (MSW spawners) salmon in Northern (NEAC-N) and Southern (NEAC-S) NEAC stock complexes.

Figure 3.3.4.3a. PFA of maturing (2021) and non-maturing (2020) in percent of spawner escapement reserve (\% of SER). The percent of SER is based on the median of the Monte Carlo distribution. The colour shading represents the three ICES stock status designations: Full (at full reproductive capacity: the 5th percentile of the spawner estimate is above the SER), At Risk (at risk of suffering reduced reproductive capacity: median spawner estimate is above the SER, but the 5th percentile is below) and Suffering (suffering reduced reproductive capacity: median spawner estimate is below the SER). For 2021, values for Russia are derived from total reported catches provided in tonnes (NASCO, 2023).

Figure 3.3.4.3b. PFA of maturing (2022) and non-maturing (2021) in percent of spawner escapement reserve (\% of SER). The percent of SER is based on the median of the Monte Carlo distribution. The colour shading represents the three ICES stock status designations: Full (at full reproductive capacity: the 5th percentile of the spawner estimate is above the SER), At Risk (at risk of suffering reduced reproductive capacity: median spawner estimate is above the SER, but the 5th percentile is below) and Suffering (suffering reduced reproductive capacity: median spawner estimate is below the SER). For 2022, values for Russia are derived from total reported catches provided in tonnes (NASCO, 2023).

Figure 3.3.4.4a. 1SW returns and spawners in percent of conservation limit (\% of CL) for 2021. The percent of CL is based on the median of the Monte Carlo distribution. The colour shading represents the three ICES stock status designations: Full (at full reproductive capacity: the 5th percentile of the spawner estimate is above the CL), At Risk (at risk of suffering reduced reproductive capacity: median spawner estimate is above the CL, but the 5th percentile is below) and Suffering (suffering reduced reproductive capacity: median spawner estimate is below the CL). For 2021, values for Russia are derived from total reported catches provided in tonnes (NASCO, 2023).

Figure 3.3.4.4b. 1SW returns and spawners in percent of conservation limit (\% of CL) for 2022. The percent of CL is based on the median of the Monte Carlo distribution. The colour shading represents the three ICES stock status designations: Full (at full reproductive capacity: the 5 th percentile of the spawner estimate is above the CL), At Risk (at risk of suffering reduced reproductive capacity: median spawner estimate is above the CL, but the 5th percentile is below) and Suffering (suffering reduced reproductive capacity: median spawner estimate is below the CL). For 2022, values for Russia are derived from total reported catches provided in tonnes (NASCO, 2023).

Figure 3.3.4.5a. MSW returns and spawners in percent of conservation limit (\% of CL) for 2021. The percent of CL is based on the median of the Monte Carlo distribution. The colour shading represents the three ICES stock status designations: Full (at full reproductive capacity: the 5th percentile of the spawner estimate is above the CL), At Risk (at risk of suffering reduced reproductive capacity: median spawner estimate is above the CL, but the 5th percentile is below) and Suffering (suffering reduced reproductive capacity: median spawner estimate is below the CL). For 2021, values for Russia are derived from total reported catches provided in tonnes (NASCO, 2023).

Figure 3.3.4.5b. MSW returns and spawners in percent of conservation limit (\% of CL) for 2022. The percent of CL is based on the median of the Monte Carlo distribution. The colour shading represents the three ICES stock status designations: Full (at full reproductive capacity: the 5th percentile of the spawner estimate is above the CL), At Risk (at risk of suffering reduced reproductive capacity: median spawner estimate is above the CL, but the 5th percentile is below) and Suffering (suffering reduced reproductive capacity: median spawner estimate is below the CL). For 2022, values for Russia are derived from total reported catches provided in tonnes (NASCO, 2023).

Figure 3.3.4.6a. 1SW returns and spawners in percent of region-specific conservation limit (\% of CL) for 2021. The percent of $C L$ is based on the median of the Monte Carlo distribution. The colour shading represents the three ICES stock status designations: Full (at full reproductive capacity: the 5 th percentile of the spawner estimate is above the CL ), At Risk (at risk of suffering reduced reproductive capacity: median spawner estimate is above the CL, but the 5th percentile is below) and Suffering (suffering reduced reproductive capacity: median spawner estimate is below the CL). For 2021, values for Russia are derived from total reported catches provided in tonnes (NASCO, 2023).

Figure 3.3.4.6b. 1SW returns and spawners in percent of region-specific conservation limit (\% of CL) for 2022. The percent of CL is based on the median of the Monte Carlo distribution. The colour shading represents the three ICES stock status designations: Full (at full reproductive capacity: the 5th percentile of the spawner estimate is above the CL), At Risk (at risk of suffering reduced reproductive capacity: median spawner estimate is above the CL, but the 5th percentile is below) and Suffering (suffering reduced reproductive capacity: median spawner estimate is below the CL). For 2022, values for Russia are derived from total reported catches provided in tonnes (NASCO, 2023).

Figure 3.3.4.7a. MSW returns and spawners in percent of region-specific conservation limit (\% of CL) for 2021. The percent of CL is based on the median of the Monte Carlo distribution. The colour shading represents the three ICES stock status designations: Full (at full reproductive capacity: the 5th percentile of the spawner estimate is above the CL), At Risk (at risk of suffering reduced reproductive capacity: median spawner estimate is above the CL, but the 5th percentile is below) and Suffering (suffering reduced reproductive capacity: median spawner estimate is below the CL). For 2021, values for Russia are derived from total reported catches provided in tonnes (NASCO, 2023).

Figure 3.3.4.7b. MSW returns and spawners in percent of region-specific conservation limit (\% of CL) for 2022. The percent of CL is based on the median of the Monte Carlo distribution. The colour shading represents the three ICES stock status designations: Full (at full reproductive capacity: the 5th percentile of the spawner estimate is above the CL), At Risk (at risk of suffering reduced reproductive capacity: median spawner estimate is above the CL , but the 5 th percentile is below) and Suffering (suffering reduced reproductive capacity: median spawner estimate is below the CL). For 2022, values for Russia are derived from total reported catches provided in tonnes (NASCO, 2023).

Figure 3.3.5.1 Time-series showing the number of rivers with established CLs (light blue dotted lines), the number of rivers assessed annually (light blue solid lines), and the number of rivers meeting CLs annually (red dotted lines) for jurisdictions in the NEAC area.

Figure 3.3.6.1. Comparison of the proportional change in the most recent five-year mean return rates compared to the previous five-year mean return rates for 1SW and 2SW wild (left hand panels) and hatchery (right hand panels) smolts to rivers of Northern (upper panels) and Southern NEAC (lower panels) areas. Populations with at least three data-points in each of the two time periods are included in the analysis. The scale of change in some rivers is influenced by very low return numbers creating high uncertainty, which may have a large consequence on the proportional change.

Figure 3.3.6.2. Least squared (marginal mean) average annual survival indices (\%) of wild (left hand panels) and hatchery origin smolts (right hand panels) of 1SW and 2SW salmon to Northern (top panels) and Southern NEAC areas (bottom panels). For most rivers in Southern NEAC, the values are returns to the coast prior to the homewater coastal fisheries. Mean annual return rates for each origin and area were estimated from a general linear model assuming quasi-Poisson errors (log-link function). Error bars represent standard errors. Trend lines are from locally weighted polynomial regression (LOESS) and are meant to be a visual interpretation aid. Following details in Tables 3.3.6.1 and 3.3.6.2 the analyses included estimated survival (\%) to 1SW and 2SW returns by smolt year

## 4 North American Commission

### 4.1 NASCO has requested ICES to describe the key events of the $\mathbf{2 0 2 1}$ and $\mathbf{2 0 2 2}$ fisheries

### 4.1.1 Key events of the 2021 and 2022 fisheries

There were no significant changes in the 2021 or 2022 fisheries.

### 4.1.2 Gear and effort

### 4.1.2.1 Canada

The 23 areas for which Fisheries and Oceans Canada (DFO) manages the salmon fisheries are called Salmon Fishing Areas (SFAs). Inner Bay of Fundy Atlantic salmon, SFA 22 and part of SFA 23, have been federally listed as endangered under the Canadian Species at Risk Act and information for these stocks are not included in the information and advice provided to NASCO, as with the exception of one population, these stocks have a localized migration strategy while at sea and a high incidence of maturity after one winter at sea. In Quebec, the management of Atlantic salmon is delegated to the province (Ministère de l'Environnement, de la Lutte contre les changements climatiques, de la Faune et des Parcs) and the fishing areas are designated by Q1 through Q11 (Figure 4.1.2.1). Harvests (fish which were retained) and catches (including harvests and fish caught and released in recreational fisheries) are categorized in two size groups: small and large. Small salmon, generally 1SW, in the recreational and subsistence fisheries refer to salmon less than 63 cm fork length. In historic commercial fisheries small salmon refer to fish less than 2.7 kg whole weight. Large salmon, generally MSW and repeat spawners, in recreational and subsistence fisheries are greater than or equal to 63 cm fork length. In historic commercial fisheries large salmon refer to fish greater than or equal to 2.7 kg whole weight.

Three groups exploited salmon in Canada in 2021 and 2022: Indigenous, Labrador resident subsistence, and recreational fishers. There are no commercial salmon fisheries in Canada and retaining bycatch of salmon in commercial fisheries targeting other species is not permitted. Salmon discards from these fisheries are not estimated, however, previous analyses by ICES indicated the extent was low (ICES, 2004). The sale of Atlantic salmon caught in any Canadian fishery is prohibited.

In 2021 and 2022, four subsistence fisheries harvested salmon in Labrador: 1) Nunatsiavut Government (NG) members fishing in northern Labrador communities (Rigolet, Makkovik, Hopedale, Postville, and Nain); and in Lake Melville communities (Northwest River, Happy Valley - Goose Bay) 2) Innu Nation members fishing in the northern Labrador community of Natuashish and Lake Melville community of Sheshatshiu; 3) NunatuKavut Community Council (NCC) members fishing in southern Labrador and Lake Melville (Licences issued from the communities of Happy Valley - Goose Bay, Cartwright and Port Hope Simpson) and, 4) Labrador residents fishing in Lake Melville and northern and southern coastal communities. The NG, Innu, and NCC fisheries were jointly monitored by Indigenous Fishery Guardians/Conservation Officers and DFO. Nylon twine is only permitted in nets, monofilament nets are strictly prohibited. The maximum length of net permitted per household is approximately $27-46$ metres, depending on management area. Only nets with a minimum mesh size of 89 mm ( 3.5 inches) and a maximum of 102 mm (4 inches) may be used in Upper Lake Melville and southern Labrador
by the NCC. Nets are generally set in estuaries and coastal bays within headlands. Catch statistics are based on logbook reports.

Most catches ( $92 \%$ in 2021 and $93 \%$ in 2022, Figure 2.1.1.2) in Canada take place in rivers or estuaries. Fisheries are principally managed on a river-by-river basis and in areas where retention of large salmon in recreational fisheries is allowed, the fisheries are closely controlled. In other areas, fisheries are managed on larger management units that encompass a collection of geographically neighbouring stocks. The commercial fisheries have remained closed since 2000 and the Labrador coastal subsistence fisheries are mainly located in bays generally inside headlands. Sampling of the Labrador subsistence fisheries continued in 2021 and 2022.
The following management measures were in effect in 2021 and 2022:

### 4.1.2.2 Indigenous food, social, and ceremonial (FSC) fisheries

In Quebec, Indigenous fisheries took place subject to agreements, conventions or through permits issued to the communities. There are approximately ten communities with subsistence fisheries in addition to the fishing activities of the Inuit in Ungava (Q11), who fished in estuaries or within rivers. The permits generally stipulate gear, season, and catch limits. Catches with permits have to be reported collectively by each Indigenous group. However, catches under a convention, such as for Inuit in Ungava, do not have to be reported. In the Maritimes (SFAs 15 to 23), FSC agreements were signed with several Indigenous groups in 2021 and 2022. The signed agreements often included allocations of small and large salmon and the area of fishing was usually in-river or estuaries. Harvests that occurred both within and outside agreements were obtained directly from the Indigenous groups. In Labrador (SFAs 1-2), FSC agreements with the NG, Innu, and NCC resulted in fisheries in estuaries and coastal areas. By agreement with First Nations, there were no FSC fisheries for salmon in Newfoundland (SFAs 3-14B) in 2021 and 2022. When fisher reports are not available, catches are estimated based on the most reliable information available (i.e. observer reports or historical data). Catch by Indigenous recreational fishers were reported under recreational fisheries.

### 4.1.2.3 Labrador resident subsistence fisheries

DFO is responsible for regulating the Labrador resident fishery. A licensed gillnet subsistence trout and charr fishery for Labrador residents takes place in estuaries and coastal areas of Labrador. A total of 260 and 248 licences were issued in 2021 and 2022, respectively. Conditions restrict a seasonal catch of three salmon of any size while fishing for trout and charr; three salmon tags accompanied each licence. Resident fishers were required to remove their nets from the water once their catch of salmon was caught. Catches exceeding three salmon must be discarded. All licensed resident fishers were requested to complete and return logbooks to DFO.

### 4.1.2.4 Recreational fisheries

Licences are required to fish recreationally for Atlantic salmon in Canada. Gear is restricted to fly fishing and there are daily and seasonal bag limits. Recreational fisheries management in 2021 and 2022 varied by area and large portions of the southern areas remained closed to all directed salmon fisheries (Figure 4.1.2.2).

Within the province of Quebec, there are 114 salmon rivers. Fishing for salmon was prohibited on 34 rivers. Large salmon could be retained throughout the season on eight rivers and for part of the season on an additional 10 rivers in 2021 and nine rivers in 2022. Small salmon could be retained during the entire season on 54 rivers in 2021 and 52 rivers in 2022. Catch and release only fishing was permitted on eight rivers in 2021 and 11 rivers in 2022. Since 2018, a seasonal permit allows a total retention of four salmon for the season, of which only one could be a large salmon. The only exception is for the four rivers located in the Ungava Bay region, where anglers
could retain four salmon of any size under the seasonal permit. A three-day permit allows for the retention of one salmon of any size. Under these permits, retention of large salmon is allowed only from rivers which are open to retention of large salmon. A catch and release permit allows fishing for catch and release only. Retention of large salmon is only permitted in Quebec.

Mandatory catch and release measures including a daily limit of two salmon were in effect in the Maritime provinces of Canada in 2021 and 2022. Newfoundland and Labrador had retention fisheries for small salmon in 2021 and 2022 with a seasonal limit of one or two salmon depending on river classification and a daily catch and release limit of three salmon.

In all areas of eastern Canada, there is no estimate of salmon released as bycatch in recreational fisheries targeting other species.

### 4.1.2.5 USA

There were no recreational or commercial fisheries for anadromous Atlantic salmon in the USA in 2021 or 2022.

### 4.1.2.6 France (Islands of Saint Pierre and Miquelon)

Four professional and 80 recreational gillnet licences were issued in 2021 and 2022 (Table 4.1.2.1). Professional licences had a maximum authorization of three nets of 360 metres maximum length each whereas recreational licences were restricted to one net of 180 metres. The selling of Atlantic salmon was only allowed by professional licence holders and was restricted to within Saint Pierre and Miquelon.

### 4.1.3 Catches

### 4.1.3.1 Canada

The provisional harvest of salmon in 2022 by all users is 99.9 t ( 97.9 in 2021), approximately $2 \%$ higher than the previous five year mean of 97.8 t (2017-2021) and $23 \%$ lower than the previous 20 year mean of 129.9 t (2002-2021) (Tables 2.1.1.1, 2.1.1.2; Figure 4.1.3.1). Canada's harvest prior to the closure of all commercial fisheries in 2000 averaged 1557 t from 1960-1999 (range: 152 t to 2863 t ).

### 4.1.3.2 Indigenous FSC fisheries

The provisional harvest by Indigenous groups in 2022 was 58.1 t ( 56.6 t in 2021), similar to the previous five year and 20 year means of 57.2 t and 57.5 t , respectively (Table 4.1.3.1).
In Labrador, total catch from Indigenous fishers was estimated by raising the reported catch from logbooks to the total number of fishers ( $64 \%$ reporting rate in 2022). For Quebec, catches from the Indigenous fisheries were to be reported collectively by each Indigenous community. As in Quebec, Indigenous groups with fishing agreements in the DFO Gulf and Maritimes regions were expected to report their catches. When reports were not available, the catches were estimated based on the most reliable information available (i.e. local enforcement officer or biologist reports or average from the last five years of available data). The reliability of the catch estimates varies among user groups. Reports in most years were incomplete or missing.

### 4.1.3.3 Labrador resident subsistence fisheries

The provisional harvest by Labrador resident fishers was 1.4 t in $2022(1.8 \mathrm{t}$ in 2021) ( $88 \%$ reporting rate in 2022), approximately $10 \%$ lower than the previous five year mean of 1.6 t and $42 \%$ less than the previous 20 year mean of 2.5 t (Table 4.1.3.2).

### 4.1.3.4 Recreational fisheries

The recreational fisheries harvest in 2022 was 40.2 t (approximately 22344 fish and $96 \%$ small salmon by number) and similar to the 2021 harvest of 39.5 (Table 4.1.3.3; Figure 4.1.3.2).
The estimated numbers of salmon caught and released in the recreational fisheries of Canada were 67056 salmon ( 47969 small and 19087 large) in 2021 and 53002 salmon ( 29650 small and 23351 large) in 2022, representing $62 \%$ and $56 \%$ of the total catch by number, respectively.
Recreational catch statistics for Atlantic salmon are not collected regularly in all areas of Canada and there is no enforceable mechanism in place that requires anglers to report their catch, except in Quebec where reporting of harvested salmon is an enforced legal requirement.

### 4.1.3.5 Commercial fisheries

All commercial fisheries for Atlantic salmon have remained closed since 2000 and the catch in 2021 and 2022 therefore was zero.

### 4.1.3.6 Unreported catches

The unreported catch for Canada was 18.4 t in 2022 ( 19.3 t in 2021) and represents an estimated catch from illegal fisheries directed at salmon (Tables 2.1.3.1, 2.1.3.2). Unreported catch for Canada was not received from all regions in 2021 and 2022 and therefore considered incomplete.

### 4.1.3.7 USA

There are no commercial or recreational fisheries for anadromous Atlantic salmon in the USA and the catch therefore was zero. Unreported catches in the USA were estimated to be 0 t .

### 4.1.3.8 France (Islands of Saint Pierre and Miquelon)

The harvest in Saint Pierre and Miquelon was 1.2 t ( 478 fish ) in 2022 ( 1.6 t or 600 fish in 2021), $29 \%$ lower than the previous five year mean (2017-2021) of 1.8 t and $57 \%$ less than the previous 20 year mean (2002-2021) of 2.9 t (Tables 2.1.1.1, 4.1.2.1). There are no unreported catch estimates for the time-series.

### 4.1.4 Harvest of North American salmon, expressed as 2SW salmon equivalents

Harvest histories (1972 to 2022) of salmon, expressed as 2 SW salmon equivalents in the 2SW return year are provided in Table 4.1.4.1. The Newfoundland and Labrador commercial fishery was historically a mixed-stock fishery and harvested both maturing and non-maturing 1SW salmon as well as 2SW maturing salmon. The harvest of repeat spawners and older sea ages was not considered in the run-reconstructions.

Harvests of 1SW non-maturing salmon in Newfoundland and Labrador commercial fisheries have been adjusted by natural mortalities of $3 \%$ per month for 13 months, and 2SW harvests in these same fisheries have been adjusted by one month to express all harvests as 2SW equivalents in the year and time they would reach rivers of origin. The Labrador commercial fishery has been closed since 1998. Harvests from the Indigenous (since 1998) and resident (since 2000) fisheries in Labrador are included. Mortalities in mixed-stock fisheries and losses in terminal locations (including harvests, losses from catch and release mortality and other removals including broodstock) in Canada were summed with those of the USA to estimate total 2SW equivalent losses in North America. The terminal fisheries included coastal, estuarine and river catches of all areas, except Newfoundland and Labrador where only river catches were included and excluding Saint Pierre and Miquelon. Data inputs were updated to 2022.

Total 2SW harvest equivalents of North American origin salmon in all fisheries peaked at 557300 fish in 1976 and was above 200000 fish in most years until 1990 (Table 4.1.4.1; Figure 4.1.4.1). Harvest equivalents within North America peaked at about 362500 in 1976 and have remained below 12000 2SW salmon equivalents for most years between 2000 and 2022 (Table 4.1.4.1; Figure 4.1.4.1). The percentage of the 2SW harvest equivalents taken in North America has varied from $42 \%$ to $63 \%$ of the total removals in all fisheries during 2008 to 2022 (Figure 4.1.4.1).

In the most recent 2SW harvest year (2022), the losses of 2SW salmon in terminal areas of North America was estimated at 8500 fish (median), $46 \%$ of the total North American catch of 2SW salmon. The percentages of harvests occurring in terminal fisheries ranged from $17 \%$ to $44 \%$ during 1973 to 1992 and $42 \%$ to $87 \%$ during 1993 to 2022 (Table 4.1.4.1). Percentages increased significantly since 1992 with the reduction and closures of the Newfoundland and Labrador commercial mixed-stock fisheries. The percentage of 2SW salmon harvested in North American fisheries in 2022 is $50 \%$ (Table 4.1.4.1). The percentages of the 2 SW harvests by fishery and fishing area are summarized in Figure 4.1.4.1. The percentage of the $2 S W$ harvest equivalents taken at Greenland was as high as $56 \%$ in 1992 and 2002 and as low as $5 \%$ in 1994 when the internal use fishery at Greenland was suspended (Figure 4.1.4.1). In the last three years, the Greenland share of the 2SW harvest equivalents has been $36 \%$ to $51 \%$. For similar years, the harvests in the Labrador subsistence fisheries have been $26 \%$ to $33 \%$ of the total harvests and $19 \%$ to $25 \%$ in terminal fisheries of Quebec (Figure 4.1.4.1).

### 4.1.5 Origin and composition of catches

In the past, salmon from both Canada and the USA were taken in the commercial fisheries of eastern Canada. Sampling programs of current marine fisheries (Labrador; Saint Pierre and Miquelon) are used to determine region of origin of harvested salmon.

### 4.1.5.1 Labrador subsistence fisheries sampling programme

Salmon harvested in the Labrador subsistence fisheries (SFAs 1 and 2, Figure 4.1.2.1) were sampled opportunistically for length, weight, sex, scales (for age analysis) and tissue (genetic analysis). Fish were also examined for the presence of external tags or marks.

In 2021, a total of 1126 samples were collected from the Labrador subsistence fisheries: 222 from northern Labrador (SFA 1A), 265 from Lake Melville (SFA 1B), and 639 from southern Labrador (SFA 2). The samples represent $7.9 \%$ of the catch by number ( $8.7 \%$ of small salmon, $5.4 \%$ of large salmon) (31 samples did not have size information).

In 2022, a total of 900 samples were collected from the Labrador subsistence fisheries: 103 from northern Labrador (SFA 1A), 88 from Lake Melville (SFA 1B), and 709 from southern Labrador (SFA 2). The samples represent $6.4 \%$ of the catch by number ( $7.8 \%$ of small salmon, $3.3 \%$ of large salmon) ( 24 samples did not have size information).

| Size group | Statistics | 2021 | 2022 |
| :---: | :---: | :---: | :---: |
| Small salmon (<63 cm) | Samples (\#) | 853 | 712 |
|  | Catch (\#) | 9758 | 9130 |
|  | \% of catch | 8.7\% | 7.8\% |
| Large salmon ( $\geq 63 \mathrm{~cm}$ ) | Samples (\#) | 242 | 164 |
|  | Catch (\#) | 4500 | 5037 |
|  | \% of catch | 5.4\% | 3.3\% |
| Total | Samples (\#) | 1126 | 900 |
|  | Catch (\#) | 14258 | 14167 |
|  | \% of catch | 7.9\% | 6.4\% |

Not all scales can be interpreted for age. In 2021, the percent sea age composition was $80 \% 1 \mathrm{SW}$, $17 \% 2$ SW, $2 \% 3$ SW and $1 \%$ previously spawned salmon. In 2022, the percent sea age composition was $84 \% 1 \mathrm{SW}, 12 \% 2$ SW and $4 \%$ previously spawned salmon. In both years, all salmon samples interpreted for river age were 2 to 7 years (modal age 4). There was no river age 1 and few riverage 2 salmon sampled suggesting that very few salmon from southern stocks of North America (USA, Scotia-Fundy) are exploited in these fisheries.

| Labrador: Sample summary 2021 and 2022 |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Area | Number of Scale Samples | River Age (percent) |  |  |  |  |  |  |
|  |  | 1 | 2 | 3 | 4 | 5 | 6 | 7 |
| 2021 |  |  |  |  |  |  |  |  |
| Northern Labrador (SFA 1A) | 195 | 0.0 | 1.5 | 11.3 | 47.2 | 33.8 | 6.2 | 0.0 |
| Lake Melville (SFA 1B) | 253 | 0.0 | 0.4 | 14.6 | 63.6 | 20.2 | 0.8 | 0.4 |
| Southern Labrador (SFA 2) | 603 | 0.0 | 1.5 | 11.8 | 54.2 | 28.7 | 3.8 | 0.0 |
| Total | 1051 | 0.0 | 1.2 | 12.4 | 55.2 | 27.6 | 3.5 | 0.1 |
| 2022 |  |  |  |  |  |  |  |  |
| Northern Labrador (SFA 1A) | 100 | 0.0 | 0.0 | 8.0 | 66.0 | 24.0 | 1.0 | 1.0 |
| Lake Melville (SFA 1B) | 85 | 0.0 | 0.0 | 10.6 | 60.0 | 25.9 | 3.5 | 0.0 |
| Southern Labrador (SFA 2) | 691 | 0.0 | 0.3 | 8.8 | 55.3 | 33.7 | 1.7 | 0.1 |
| Total | 876 | 0.0 | 0.2 | 8.9 | 57.0 | 31.8 | 1.8 | 0.2 |

The majority of tissue samples collected in 2021 (96\%) and 2022 (97\%) from the Labrador subsistence fisheries were analysed for genetic origin (Figure 4.1.5.3). A total of 1079 tissue samples were analysed from 2021 and 872 from 2022 using the SNP panel with 31 range-wide reporting groups (Table 4.1.5.1; Figures 4.1.5.1, 4.1.5.2). The estimated percent contributions (and associated $95 \%$ credible interval) to each reporting group in 2021 and 2022 are shown in Tables 4.1.5.2 and 4.1.5.3, respectively, and summarized in Figures 4.1.5.4 and 4.1.5.5. As in previous years, the estimated origin of the samples was dominated ( $>95 \%$ ) by the Labrador reporting groups. The dominance of the Labrador reporting groups is consistent with previous analyses conducted since 2006 which estimated $>95 \%$ of the catch was attributable to Labrador stocks (ICES, 2019, 2020). Furthermore, assignment of harvest within the Labrador genetic reporting groups suggest largely local harvest within salmon fishing areas.

### 4.1.5.2 Saint Pierre and Miquelon fisheries sampling programme

The number of samples collected in the Saint Pierre and Miquelon fishery was 116 in $2020(19 \%$ of the catch), 51 in 2021 ( $9 \%$ of the catch) and 29 in 2022 ( $6 \%$ of the catch). Based on the interpretation of the scale samples, $100 \%$ of the small salmon samples were 1 SW and the majority of large salmon samples were 2 SW ( $90 \%-100 \%$ ). River ages ranged from one to five years (modal age 3).

| Saint Pierre and Miquelon: Sample summary 2020 to 2022 |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Size group | Number of Samples (\#) | Percent of Samples (\%) | Virgin Sea Age (\%) |  | River Age (\%) |  |  |  |  |
|  |  |  | 1SW | 2SW | 1 | 2 | 3 | 4 | 5 |
| 2020 |  |  |  |  |  |  |  |  |  |
| Small salmon (<63 cm) | 65 | 57.0 | 100.0 | 0.0 | 0.0 | 20.0 | 44.6 | 32.3 | 3.1 |
| Large salmon ( $\geq 63 \mathrm{~cm}$ ) | 49 | 43.0 | 8.2 | 91.8 | 2.0 | 44.9 | 44.9 | 8.2 | 0.0 |
| Total | 114 | 100.0 | 60.5 | 39.5 | 0.9 | 30.7 | 44.7 | 21.9 | 1.8 |
| 2021 |  |  |  |  |  |  |  |  |  |
| Small salmon (<63 cm) | 33 | 64.7 | 100.0 | 0.0 | 0.0 | 12.1 | 72.7 | 12.1 | 3.0 |
| Large salmon ( $\geq 63 \mathrm{~cm}$ ) | 18 | 35.3 | 0.0 | 100.0 | 0.0 | 33.3 | 61.1 | 5.6 | 0.0 |
| Total | 51 | 100.0 | 64.7 | 35.3 | 0.0 | 19.6 | 68.6 | 9.8 | 2.0 |
| 2022 |  |  |  |  |  |  |  |  |  |
| Small salmon (<63 cm) | 9 | 31.0 | 100.0 | 0.0 | 0.0 | 33.3 | 55.6 | 11.1 | 0.0 |
| Large salmon ( $\geq 63 \mathrm{~cm}$ ) | 20 | 69.0 | 10.0 | 90.0 | 0.0 | 45.0 | 50.0 | 5.0 | 0.0 |
| Total | 29 | 100.0 | 37.9 | 62.1 | 0.0 | 41.4 | 51.7 | 6.9 | 0.0 |

All of the tissue samples collected in the Saint Pierre and Miquelon fishery 2020 to 2022 were analysed for genetic origin (Figure 4.1.5.3) using the SNP panel with 31 range-wide reporting groups (Table 4.1.5.1; Figures 4.1.5.1, 4.1.5.2). The estimated percent contributions (and associated $95 \%$ credible interval) to each reporting group from 2020 to 2022 are shown in Tables 4.1.5.4 and summarized in Figures 4.1.5.6 to 4.1.5.8. The estimated origin of the samples was dominated ( $>94 \%$ ) by the reporting groups in Quebec (4 groups), Gulf (one group) and Newfoundland (7 groups). Large salmon were mainly ( $>77 \%$ ) from the Quebec and Gulf groups and the largest portion ( $>48 \%$ ) of the small salmon were from Newfoundland groups.

### 4.1.6 Exploitation rates

### 4.1.6.1 Canada

For Newfoundland, mean exploitation rate in the recreational fishery for retained small salmon was $4.9 \%$ in 2021 (ten rivers: range of $0 \%$ to $14.5 \%$ ). Provisional mean exploitation rate in the 2022 recreational fishery for retained small salmon was $8.8 \%$ (ten rivers; range of $0 \%$ to $19.8 \%$ ), an increase from the previous five-year mean of $11 \%$. In Quebec, total fishing exploitation rate was estimated at $13.6 \%$ in 2021 and $12.9 \%$ in 2022, the lowest values since 1984. Exploitation rate for the Indigenous fishery was $5.6 \%$ in 2021 and $6.1 \%$ in 2022. Exploitation rate for the recreational fishery was $7.3 \%$ in 2021 and $6.8 \%$ in 2022. The recreational exploitation rate for large salmon in Quebec was $2.1 \%$ in 2021 and $2.7 \%$ in 2022, among the lowest values since 1984; it is mostly influenced by the increase in the number of released fish in recent years. Retention of small and large salmon in the recreational fisheries of Nova Scotia, New Brunswick and Prince Edward Island was not permitted in 2021 and 2022.

### 4.1.6.2 USA

There was no exploitation of anadromous salmon in homewaters.

### 4.1.6.3 Exploitation trends for North American salmon fisheries

Annual exploitation rates of small salmon (mostly 1SW) and large salmon (mostly MSW) in North America for the 1971 to 2022 time period were calculated by dividing annual estimated losses (harvests, estimated mortality from catch and release (ICES, 2010), broodstock removals) in all areas of North America by annual estimates of the returns to North America prior to any homewater fisheries. The fisheries included coastal, estuarine and river fisheries in all areas, as
well as the commercial fisheries of Newfoundland and Labrador, which harvested salmon from all regions in North America.

Exploitation rates of both small and large salmon fluctuated annually but remained relatively steady until 1984 when exploitation of large salmon declined sharply with the introduction of the non-retention of large salmon in angling fisheries and reductions in commercial fisheries (Figure 4.1.6.1). Exploitation of small salmon declined steeply in North America with the closure of the Newfoundland commercial fishery in 1992. Declines continued in the 1990s with continuing management controls in all fisheries to reduce exploitation. In the last ten years, exploitation rates on small salmon and large salmon have remained at the lowest in the time-series, averaging $9 \%$ for large salmon and $11 \%$ for small salmon. However, exploitation rates across regions within North America are highly variable.

### 4.2 Management objectives and reference points

Management objectives are described in Section 1.4 and reference points and the application of precaution are described in Section 1.5.
Fisheries and Oceans Canada (DFO) undertook a revision of reference points for Atlantic salmon in Canada that conform to the Precautionary Approach (ICES, 2016). The Limit Reference Points in all cases are defined by total eggs from all sizes and sea ages of salmon. DFO Newfoundland Region retained the current conservation requirement based on 240 eggs per $100 \mathrm{~m}^{2}$ of fluvial rearing habitat, and in addition for insular Newfoundland 368 eggs per ha of lacustrine habitat (or 150 eggs per ha for stocks on the northern peninsula of Newfoundland), as equivalent to their Limit Reference Point and have defined the Upper Stock Reference as $150 \%$ of the Limit Reference Point (DFO, 2017). DFO Maritimes Region (Scotia-Fundy) has retained the current conservation requirement based on 240 eggs per $100 \mathrm{~m}^{2}$ as the Limit Reference Point (DFO, 2012; Gibson and Claytor, 2013). DFO Gulf Region revised and defined the Limit Reference Point in that region of Canada using the proportion of eggs from MSW salmon as a covariate in the Bayesian Hierarchical Model (DFO, 2018) and defined the Upper Stock Reference as 3.78 times the Limit Reference point (Chaput et al., 2023). The Province of Quebec revised the Limit Reference point and Upper Stock Reference point using a Bayesian hierarchical analysis of stock-recruitment data (Dionne et al., 2015; MFFP, 2016; ICES, 2017). For Quebec, the management plan for recreational fishery provides river-specific Upper Stock Reference points, expressed in number of eggs, to regulate large salmon retention (MFFP, 2016). As previously described (ICES 2019a), this Upper Stock Reference point is also used to establish the 2 SW spawner requirement for advice on the management of the 1SW non-maturing fisheries at Greenland.

| Country and <br> Commission Area | Stock Area | 2SW spawner <br> requirement <br> (number of fish) | 2SW Management <br> Objective <br> (number of fish) |
| :--- | :--- | :--- | :--- |
| Canada | Labrador (LAB) | 34746 |  |
|  | Newfoundland (NFLD) | 4022 |  |
|  | Quebec (QC) | 32085 | 10976 |
| Southern Gulf of St Lawrence (GULF) | 18737 | 4549 |  |
| Canada Total | Scotia-Fundy (SF) | 24705 |  |
| USA Total |  | 114295 |  |
| North America Total |  | 29199 |  |

### 4.2.1 Recommendations for future activities of the Working Group

The Working Group recommends evaluating how 2SW spawner requirement should be estimated and applied, especially for jurisdictions that have both Limit Reference Points and Upper Stock Reference points. Currently in NAC, some jurisdictions' 2SW spawner requirements are based on a Limit Reference Point while others are based on an Upper Stock Reference point. These varying approaches raise consistency issues and should be addressed.

### 4.3 Status of stocks

Based on information provided in the update (2018) of the NASCO Database of Salmon Rivers, a total of 857 rivers have been identified in eastern Canada. There are 21 rivers in eastern USA where salmon are or were present within the last half century. Conservation requirements have been defined for 498 ( $58 \%$ ) of these rivers in eastern Canada and all rivers in USA. Assessments of adult spawners and egg depositions relative to conservation requirements were reported for 73 rivers in eastern North America in 2020.

### 4.3.1 Smolt abundance

### 4.3.1.1 Canada

Wild smolt production was estimated in eight rivers in 2021 and ten rivers in 2022 (Table 4.3.1.1). In 2022, the relative smolt production, standardized to the size of the river using the CL egg requirements, was highest in St Jean River (Quebec) and lowest in Rocky River (Newfoundland) (Figure 4.3.1.1). Trends in smolt production over the time-series declined ( $\mathrm{p}<0.05$ ) in the Nashwaak River (Scotia-Fundy, 1998-2022), St Jean River (Quebec 1989-2022), de la Trinité River (Quebec, 1984-2022) and Conne River (Newfoundland, 1987-2022), whereas production significantly increased ( $\mathrm{p}<0.05$ ) in Western Arm Brook (Newfoundland, 1971-2022). No other rivers showed statistically significant long-term trends (Figure 4.3.1.1).

### 4.3.1.2 USA

Wild Smolt production was estimated on the Narraguagus River in 2021 and 2022 (Table 4.3.1.1; Figure 4.3.1.1). Smolt production has declined over time ( $\mathrm{p}<0.05$ ) on this river (1997-2022).

### 4.3.2 Estimates of total adult abundance

Returns of small (1SW), large (MSW), and 2SW salmon (a subset of large) to each region were originally estimated by the methods and variables developed by Rago et al. (1993) and reported by ICES (1993). Further details are provided in the Stock Annex (Annex 5). The returns for individual river systems and management areas for both sea age groups were derived from a variety of methods. These methods included counts of salmon at monitoring facilities, population estimates from mark-recapture studies, and applying angling and commercial catch statistics, angling exploitation rates, and measurements of freshwater habitat. The 2SW component of the large returns was determined using the sea age composition of one or more indicator stocks.
Returns are the number of salmon that returned to the geographic region, including fish caught by homewater commercial fisheries, except in the case of the Newfoundland and Labrador regions where returns do not include landings in mixed stock commercial and subsistence fisheries. This avoided double counting fish because commercial catches in Newfoundland and Labrador and subsistence fisheries in Labrador were added to the sum of regional returns to create the pre-fishery abundance estimates (PFA) of North American salmon.

Total returns of salmon to USA rivers are the sum of trap catches and redd-based estimates.
Data from previous years were updated and corrections were made to data inputs when required (e.g. 2014-2021 data were corrected and finalized). In 2020, some regions were affected by the COVID-19 global pandemic and had to either modify the way returns estimates were produced (e.g. SFA15 using snorkel counts of spawners instead of angling data) or could not provide returns estimates (e.g. SFA 16, 17, 18, 19-21 and 23). When no data were available, the previous five-year mean was used for all SFAs, except for Newfoundland where the previous six-year mean was used.

Since 2002, Labrador regional estimates are generated from data collected at four counting facilities, one in SFA 1 and three in SFA 2 (Figures 4.1.2.1, 4.3.2.1). The current method to estimate Labrador returns assumes that the total returns to the northern area are represented by returns at the single monitoring facility in SFA 1 and returns in the southerly areas (SFA 2 and 14B) are represented by returns at the three monitoring facilities in SFA 2. The production area $\left(\mathrm{km}^{2}\right)$ in SFA 1 is approximately equal to the combined production areas in SFA 2 and 14B. The uncertainty in the estimates of returns and spawners has been relatively high compared with other regions in recent years.

Estimates of small, large and 2SW salmon returns to the six geographic areas and overall, for NAC are reported in Tables 4.3.2.1 to 4.3.2.3 and are shown in Figures 4.3.2.2 to 4.3.2.4.

### 4.3.2.1 Small salmon returns

- The total estimate of small salmon returns to North America in 2022 (540 700) ranks seventh highest of the 52-year time-series.
- Small salmon returns in 2022 decreased from the previous year in all regions ( $-25 \%$ to $62 \%$ ) but in Labrador and the USA
- Small salmon returns in 2022 were the highest in the time-series for Labrador and among the lowest for Gulf and Scotia-Fundy (both fourth lowest).
- In 2022 (and similarly to the last five years), small salmon returns to Labrador (335 500) and Newfoundland (160400) combined represented $92 \%$ of the total small salmon returns to North America.
Increased estimated abundance of small salmon in Newfoundland over the time-series is not reflected in all areas of Newfoundland (Figure 4.3.2.5). Estimated abundance has increased in the salmon fishing areas of the northeast coast of Newfoundland (SFA 3-5) and the western portion of the island (SFA 13 and 14A) while estimated abundances have declined on the south coast (SFA 10-12) and the eastern portion of the island (SFA 6-9). Changes in the recreational fisheries management measures in recent years have resulted in lower catches and as a result increased the uncertainty in the Salmon Fishing Area-specific estimates of abundance.

### 4.3.2.2 Large salmon returns

- The total estimated large salmon return to North America in 2022 of 188800 fish was the thirteenth of the 52-year time-series beginning in 1971.
- Large salmon returns in 2022 increased from the previous year in Labrador (72\%), Quebec ( $10 \%$ ), Gulf ( $69 \%$ ), Scotia-Fundy ( $179 \%$ ) and USA ( $159 \%$ ).
- Large salmon returns in 2022 were the second highest ( 84700 ) of the 52-year time-series for Labrador.
- On average (2018-2022), large salmon returns to USA and Scotia-Fundy combined represented less than $2 \%$ of the total large salmon returns to North America.

### 4.3.2.3 2SW salmon returns

- The total estimate of 2SW salmon returns to North America in 2022 was 114000.
- $\quad 2 S W$ salmon returns increased from the previous year in Labrador (71\%), Quebec (10\%), Gulf ( $61 \%$ ), Scotia-Fundy ( $169 \%$ ), and USA ( $163 \%$ ).
- On average (2018-2022), the majority of 2SW salmon returns (92\%) to NAC were from Labrador ( $36 \%$ ), Quebec ( $28 \%$ ), and Gulf ( $28 \%$ ). There are few 2 SW salmon returns to Newfoundland (5\%), as the majority of the large salmon returns to that region are comprised of previously spawned 1SW salmon. Scotia-Fundy and USA each represent less than $1 \%$ of NAC 2 SW returns respectively.

### 4.3.3 Estimates of spawning escapements

Updated estimates for small, large and 2SW salmon spawners (1971 to 2022) were derived for the six geographic regions (Tables 4.3.3.1 to 4.3.3.3). A comparison between the numbers of returns and spawners for small and large salmon is presented in Figures 4.3.2.2 and 4.3.2.3. A comparison between the numbers of 2SW returns, spawners, CLs, and management objectives (Sco-tia-Fundy and USA) is presented in Figure 4.3.2.4. For Quebec, 2SW CL correspond to the Upper Stock Reference point.

### 4.3.3.1 Small salmon spawners

- The total estimate of small salmon spawners in 2022 for North America (515 400) ranks fourth highest of the 52-year time-series.
- Estimates of small salmon spawners decreased in 2022 from the previous year in all areas ( $-27 \%$ to $-65 \%$ ) but Labrador and the USA ( $77 \%$ and $60 \%$, respectively).
- Small salmon spawners in 2022 were the highest on record for Labrador.
- On average of the previous five years, small salmon spawners for Labrador (222 400) and Newfoundland (211500) combined represented $88 \%$ of the total small salmon spawners estimated for North America.

### 4.3.3.2 Large salmon spawners

- The total estimate of large salmon spawners in North America for 2022 (183 700), the third highest amount in the 52-year time-series.
- Estimates of large salmon spawners increased from 2021 in all areas ( $11 \%$ to $238 \%$ ) but Newfoundland Labrador (-43\%).
- Large salmon spawners in 2022 were the second highest on record for Labrador.

### 4.3.3.3 2SW salmon spawners

- The total estimate of 2SW salmon spawners in North America for 2022 was 110400 and was below the combined 2SW CL for NAC (143 494).
- Estimates of 2 SW salmon spawners increased from 2021 in in all areas ( $11 \%$ to $243 \%$ ) but Newfoundland (-53\%).
- 2SW salmon spawners to NAC in 2020 were the sixth highest on record (1971-2022; 52 years).
- Estimates (median) of 2SW salmon spawners were below the region-specific 2SW CLs in Newfoundland ( $93 \%$ of CL), Quebec ( $72 \%$ of CL), Scotia-Fundy ( $8 \%$ of CL) and USA ( $5 \%$ of CL). The estimated 2SW spawners in Labrador have exceeded the 2SW CL seven times since 2011. The 2SW CLs were last exceeded in 2021 for Newfoundland, in 1982 for Quebec. The 2SW CLs have never been exceeded for Scotia-Fundy and USA over the entire time-series.
- The 2SW management objectives have not been met since 1991 for Scotia-Fundy, and 2013 for USA. For USA, 2SW returns are assessed relative to the management objective
as adult stocking programmes for restoration efforts contribute to the number of spawners.

### 4.3.4 Egg depositions

Egg depositions by all sea ages combined in 2021 exceeded or equalled the river-specific CLs in 39 of the 87 assessed rivers ( $45 \%$ ) and were less than $50 \%$ of CLs in 37 rivers ( $43 \%$ ) (Figure 4.3.4.1). Egg depositions by all sea ages combined in 2022 exceeded or equalled the river-specific CLs in 45 of the 83 assessed rivers ( $54 \%$ ) and were less than $50 \%$ of CLs in 25 rivers ( $30 \%$ ) (Figure 4.3.4.1). Large deficiencies in egg depositions ( $<10 \%$ CLs) were noted in 18 assessed rivers ( $21 \%$ ) in 2021 and in 12 assessed rivers ( $14 \%$ ) in 2022.

- In 2021, CLs were met or exceeded in three of four (75\%) assessed rivers in Labrador, seven of 14 rivers ( $50 \%$ ) in Newfoundland, 27 of 36 rivers ( $75 \%$ ) in Quebec and two of 12 rivers $(17 \%)$ in Gulf and zero of seven in Scotia-Fundy.
- In 2022, CLs were met or exceeded in three of four (75\%) assessed rivers in Labrador, six of 15 rivers $(40 \%)$ in Newfoundland, 32 of 36 rivers ( $89 \%$ ) in Quebec and three of seven rivers ( $43 \%$ ) in Gulf and one of seven rivers ( $14 \%$ ) in Scotia-Fundy.
- Large deficiencies in egg depositions were noted in the USA. All 14 rivers for which proportion of their CLs was assessed were below $30 \%$ of their CLs (with the exception of Kennebec River). All anadromous Atlantic salmon fisheries in the USA are closed.

CLs for the US were first estimated by ICES (1995) and were representative of accessible habitat at that time. As such, the CL for the Kennebec River in southern US is estimated as 67 2SW spawners. The Kennebec River contains a significant amount of spawning and rearing habitat within the drainage and in recent years significant restoration activities involving trucking prespawned adult salmon captured at the lowermost main-stem dam and egg planting activities has resulted in modest number of spawners being located within the Sandy River, a tributary to the Kennebec. The habitat within the Sandy River was not considered within the estimated CL for the Kennebec estimated in 1995, which is why the percent CL achieved is so high for this system. Given situations like this and other evolving management activities and priorities, the US is working to update the CLs based on the best available information and these updated CLs will be used to track attainment of CLs in the future.

The time-series of attained CLs for assessed rivers is presented in Table 4.3.4.1 and Figure 4.3.4.2. The time-series includes all assessed small rivers on Prince Edward Island (SFA 17) individually and an additional three partially assessed rivers in the USA.

- In Canada, CLs were first established in 1991 for 74 rivers. Since then the number of rivers with defined CLs increased to 266 in 1997 and to 498 since 2018. The number of rivers assessed annually has ranged from 57 to 91 and the annual percentages of these rivers achieving CL has ranged from $26 \%$ to $70 \%$ with no temporal trend.
- Conservation limits have been established for 33 river stocks in the USA since 1995. Sixteen of these are assessed against CL attainment annually with none meeting CLs to date. The proportion of the conservation requirement attained is only presented in Figure 4.3.4.1 for the fourteen rivers with the most precise adult abundance estimates.

### 4.3.5 Return rates

In 2022, return rate estimates were available from nine wild and one hatchery populations from rivers distributed among Newfoundland, Quebec, Scotia-Fundy, and USA (Tables 4.3.5.1 to 4.3.5.4). In 2021, return rate estimates were available from two wild populations from rivers in Quebec and one hatchery population from the USA.

In 2022, the return rates of wild 2SW salmon to the Saint Jean and de la Trinité River (Quebec) were $3.14 \%$ and $0.57 \%$, respectively (Table 4.3.5.2; Figure 4.3.5.1). The return rates of wild small salmon to these rivers in 2022 were $0.74 \%$ and $0.48 \%$, respectively. The return rate of small salmon in 2022 was $1.1 \%$ for LaHave River (Scotia-Fundy) and rates ranged from 1.2\% (Conne River) to $10.7 \%$ (Western Arm Brook) for rivers in Newfoundland (Table 4.3.5.1; Figure 4.3.5.1).

In 2022, the return rate of hatchery-origin 2SW salmon to the Penobscot River (USA) was 0.17\% (Table 4.3.5.4; Figure 4.3.5.2). The return rate of hatchery-origin small salmon to this river was $0.06 \%$ in 2022 (Table 4.3.5.3; Figure 4.3.5.2).

Regional least squared (or marginal mean) mean annual return rates were calculated to balance for variation in the annual number of contributing experimental groups through application of a GLM (generalised linear model) with survival related to smolt year and river with a quasiPoisson distribution (log-link function) (Figures 4.3.5.1 and 4.3.5.2). The time-series of regional return rates of wild and hatchery smolts to small salmon and 2SW salmon by area for the period of 1970 to 2021 (Tables 4.3.5.1 to 4.3.5.4; Figures 4.3.5.1 and 4.3.5.2) indicate the following:

- Return rates of wild smolts exceed those of hatchery released smolts;
- Small salmon return rates in 2022 for Newfoundland populations, with the exception of Conne River, were greater than those for other populations in eastern North America;
- Small salmon return rates to rivers in Newfoundland have been stable over the period 1970 to 2022 (1SW).
- Small salmon (1SW) return rates of wild smolts for Quebec vary annually and have declined over the period 1983/1984 to 2021/2022 (1SW, p < 0.05). Large salmon return rates of wild smolts in this region vary annually without a statistically significant trend;
- Small salmon and 2SW return rates of wild smolts to the Scotia-Fundy vary annually and without a statistically significant trend over the period mid-1990s to 2021. However, individual river trends for Scotia-Fundy may vary from the overall trend (e.g. declines in return rates to Southern Upland index rivers; DFO, 2013);
- In USA, hatchery-origin smolt return rates to 2SW salmon have decreased over the period 1970 to 2022 ( $2 \mathrm{SW}, \mathrm{p}$ < 0.001) while 1SW return rates have remained low without any statistically significant trend.

### 4.3.6 Pre-fisheries abundance (PFA)

### 4.3.6.1 North American run-reconstruction model

The run-reconstruction model developed by Rago et al. (1993) and described in previous Working Group reports (ICES, 2008; 2009) and in the primary literature (Chaput et al., 2005) was used to estimate returns and spawners by size (small salmon, large salmon) and sea age group (2SW salmon) to the six geographic regions of NAC. The input data were similar in structure to the data used previously by the Working Group (ICES, 2012; Stock Annex 5). Estimates of returns and spawners to regions were provided for the time-series to 2022. The full set of data inputs are included in the Stock Annex 5 and the summary output tables of returns and spawners by sea age or size group are provided in Tables 4.3.2.1 to 4.3.2.3 and 4.3.3.1 to 4.3.3.3.

### 4.3.6.2 Non-maturing 1SW salmon

The non-maturing component of 1SW salmon, destined to be 2SW returns (excluding 3SW and previous spawners) is represented by the PFA estimate for year i designated as PFANAC1SW. This annual PFA is the estimated number of salmon in the North Atlantic on 1 August of the second summer at sea. As the PFA estimates for potential 2SW salmon requires estimates of returns to rivers, the most recent year for which an estimate of PFA is available is 2021. This is because PFA estimates for 2022 require 2SW returns to rivers in North America in 2023.

The PFA estimates accounting for returns to rivers, fisheries at sea in North America, fisheries at West Greenland, and corrected for natural mortality are shown in Figure 4.3.6.1 and Table 4.3.6.1. The median of the estimates of non-maturing 1SW salmon in 2021 was 17600 salmon ( $90 \%$ C.I range 138900 to 218400 ). This value is $42 \%$ higher than the revised value for 2020 (124 400) and $27 \%$ higher than the previous five-year mean (138 900). The estimated non-maturing 1SW salmon in 2021 is the twenty seventh highest of the 51-year time-series.

### 4.3.6.3 Maturing 1SW salmon

Maturing 1SW salmon are in some areas (particularly Newfoundland) a major component of salmon stocks, and their abundance when combined with that of the $2 S W$ age group provides an index of the majority of an entire smolt cohort.

The reconstructed distribution of the PFA of the 1SW maturing cohort of North American origin is shown in Figure 4.3.6.1 and Table 4.3.6.1. The estimated PFA of the maturing component in 2022 was 566200 fish, $12 \%$ above the previous five-year mean (505 400). Maximum abundance of the maturing cohort was estimated at over 910700 fish in 1981 and the recent estimate is the ninth highest of the 52-year time-series of estimated abundance.

### 4.3.6.4 Total 1 SW recruits (maturing and non-maturing)

The pre-fishery abundance of 1SW maturing salmon and 1SW non-maturing salmon from North America from 1971-2021 (2022 PFA requires 2SW returns in 2023) were summed to give total recruits of 1SW salmon (Figure 4.3.6.1; Table 4.3.6.1). The PFA of the 1SW cohort, estimated for 2021, was 886900 fish, $40 \%$ higher than the previous five-year mean ( 633 800). The 2021 PFA estimate is the eighteenth highest in the 51-year time-series. The abundance of the 1 SW cohort has declined by $48 \%$ over the time-series from a peak of 1706300 fish in 1975.

### 4.3.7 Summary on status of stocks

The status of Atlantic salmon stocks in North America to 2022 shows a steady increase in the number of small salmon, mainly driven by returns to the Labrador region, and no apparent trend for large salmon.

In 2021, the median estimates of 2 SW returns and spawners to rivers were below the respective 2SW CLs in five assessment regions of NAC, and are therefore suffering reduced reproductive capacity whereas Newfoundland was the only region that was above the 2SW CL (Figure 4.3.7.1). In 2022, four assessment regions of NAC were suffering reduced reproductive capacity whereas estimates in Labrador and Gulf were above the 2SW CLs (Figure 4.3.7.2). It should be noted that the 2SW CL for Quebec corresponds to the Upper Stock Reference whereas other regions use the Lower Stock Reference. The percentage (based on medians) of CLs attained from 2SW spawners in 2022 ranged from less than $10 \%$ in Scotia-Fundy and the USA to $158 \%$ in Labrador. For 2SW salmon returns to rivers prior to in-river exploitation, the percentages of CL attained were minimally higher. The returns of 2SW salmon to the two southern areas (Scotia-Fundy and USA) were $33 \%$ and $19 \%$, respectively, of the management objectives for these areas. For USA, 2SW
returns are assessed relative to the management objective as adult stocking programmes for restoration efforts contribute to the number of spawners.

The rank of the estimated returns in the 1971 to 2022 time-series and the proportions of the 2SW CLs achieved in 2022 for six assessment regions in North America are shown below.

| Region | Rank of 2022 returns in 1971 to 2022 (51=lowest rank) |  | Rank of 2022 returns in 2013 to 2022 (10=lowest rank) |  | Median estimate of $\mathbf{2 0 2 2}$ 2SW spawners as percentage of Conservation Limit (\% of management objective) |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | 1SW | 2SW | 1SW | 2SW | (\%) |
| Labrador | 1 | 2 | 1 | 2 | 158 |
| Newfoundland | 33 | 24 | 9 | 6 | 93 |
| Quebec | 29 | 28 | 5 | 6 | 72 |
| Gulf | 46 | 28 | 7 | 5 | 134 |
| Scotia- <br> Fundy | 49 | 39 | 8 | 2 | 8 (19) |
| USA | 21 | 29 | 2 | 2 | 5 (33) |

Estimates of PFA indicate continued low abundance of North American adult Atlantic salmon. The total population of 1SW and 2SW Atlantic salmon in the Northwest Atlantic has shown an overall declining trend since the 1970s with a period of persistent low abundance since the early 1990s. During 1992 to 2021 (moratorium in effect), the total population of 1SW and 2SW Atlantic salmon was 622700 fish, less than half of the mean abundance ( 1252000 fish) during 1971 to 1991.

The estimated maturing 1SW salmon abundance in 2022 of 566200 fish is $20 \%$ lower than the 2021 estimate and the ninth highest abundance of the 52-year time-series, beginning in 1971. Overall, $92 \%$ of 1SW (small) salmon returns to NAC in 2022 were from two regions (Labrador and Newfoundland).
The non-maturing 1SW PFA for 2021 (fish mostly destined to be 2SW salmon in 2022) increased by $41.9 \%$ from 2020, and is the twenty fifth lowest of the 51 -year time-series. Over the previous five years, $92 \%$ of 2 SW salmon returns to NAC were from three regions (Gulf, Labrador and Québec).

The estimates of 1SW (small) salmon returns in 2022 increased from 2021 in Labrador and in the USA (the abundance in the USA are in hundreds of fish vs. hundreds of thousands in Labrador). Returns to rivers (after commercial fisheries in Newfoundland and Labrador) of 1SW salmon have generally increased over the time-series for the NAC, mainly as a result of the commercial fishery closures in 1992 and subsequently in 1998. Important variations in annual abundances continue to be observed, such as the low returns of 2009 and 2013 and the high returns of 2011, and 2021 (Figure 4.3.2.2). Increased returns in recent years were estimated for Labrador and Newfoundland, which have contributed to this increasing trend for NAC. The estimated 1SW salmon returns in Labrador have increased substantially over the time-series, the estimated returns in 2022 were the highest of the 52-year time-series. Estimated returns of 1SW salmon to Newfoundland was the ninth lowest of the last ten years.

The abundances of large salmon (MSW salmon including maiden and repeat spawners) returns in 2022 relative to 2021 increased in all areas but Newfoundland.

Wild smolt-to-adult return rates to monitored rivers in eastern North America remain low, with 2021 smolt to 1 SW salmon returns ranging from $0.5 \%$ for multi-sea-winter salmon stocks to $10.7 \%$ for 1SW salmon stocks and return rates of smolts in 2020 to 2 SW salmon for the two rivers with data ranging from $0.6 \%$ to $3.1 \%$. A number of monitoring programs have been impacted by COVID-19 pandemic, in particular in 2020, which weakens the critical metrics of adult return rates for the few monitored populations.
Egg depositions by all sea ages combined in 2022 exceeded or equalled the river-specific CLs in 45 of the 83 assessed rivers ( $54 \%$ ) and were less than $50 \%$ of CLs in 25 rivers ( $30 \%$ ). Large deficiencies in egg depositions ( $\leq 10 \%$ CLs) were noted in multiple (12) rivers in the Scotia-Fundy and USA areas.
Despite major changes in fisheries, returns to the southern regions of NAC (Scotia-Fundy and USA) remain near historical lows and many populations are currently at risk of extirpation. All salmon stocks within the USA and the Scotia-Fundy regions have been or are being considered for listing under country specific species at risk legislation. Recovery Potential Assessments for the three Designable Units of salmon in Scotia-Fundy as well as for one Designable Unit in Quebec and one in Newfoundland occurred in 2012 and 2013 to inform the requirements under the Species at Risk Act listing process in Canada (ICES, 2014).

Based on previous five years, regional return estimates are reflective of the overall return estimates for NAC, as Labrador and Newfoundland collectively comprised $92 \%$ of the small salmon returns, whereas Labrador, Québec, and Gulf collectively comprised $77 \%$ of the large salmon returns and $92 \%$ of the 2SW salmon returns to NAC.

Overall, the estimated PFA of 1SW non-maturing salmon in 2021 was the twenty fifth lowest of the 51-year time-series and the estimated PFA of 1SW maturing salmon was the ninth highest of the 51-year time-series. The continued low and declining abundance of salmon stocks across North America, despite significant fishery reductions, strengthens the conclusions that factors acting on survival in the first and second years at sea at both local and broad ocean scales are constraining abundance of Atlantic salmon. Declines in smolt production in some rivers of eastern North America are now being observed and are also contributing to lower adult abundance.

Table 4.1.2.1. The number of professional and recreational gillnet licences issued and reported landings in Saint Pierre and Miquelon, 1990 to 2022. The data for 2022 are provisional.

| Year | Number of licences |  | Reported landings (t) |  |  |

Table 4.1.4.1. Reported harvests and losses expressed as 2 SW salmon equivalents (number of fish X 1000) in North American salmon fisheries for the period 1972 to 2022 , year of $\mathbf{2 S W}$ harvests in North America. Only midpoints of the Monte Carlo simulated values are shown. Geographic locations are: SPM = Saint-Pierre and Miquelon, LAB = Labrador, NF = Newfoundland, QC = Quebec, GF = Gulf, SF = Scotia-Fundy

Variations in numbers from previous assessments are due to updates to data inputs and to stochastic variation from Monte Carlo simulation.
NF-LAB comm / subs 1SW (Year i-1) = Catch of 1SW non-maturing * 0.677057 (M of 0.03 per month for 13 months to July for Canadian terminal fisheries).
NF-LAB comm / subs 2SW (Year i) = catch of 2 SW salmon * 0.970446 ( M of 0.03 per month for 1 month to July of Canadian terminal fisheries).
Canada: Losses from all sources $=2$ SW returns - 2SW spawners (includes losses from harvests from catch and release mortality and other in-river losses such as bycatch mortality but excludes the fisheries at St-Pierre and Miquelon and NF-LAB comm / subs fisheries).
a - starting in 1998 there was no commercial fishery in Labrador; numbers reflect harvests of the Indigenous and residential subsistence fisheries
Greenland total catch = estimated catch in year i-1 of 1SW non-maturing salmon of North American origin at Greenland * 0.719 which is the discounted catch for 11 months of mortality at sea as returning 2SW salmon to eastern North America (M of 0.03 per month for 11 months).

Table 4.1.5.1. Correspondence between ICES areas used for the assessment of status of North American salmon stocks and the reporting groups (Figure 4.1.5.1 and Figure 4.1.5.2) defined using the SNP range wide baseline (Jeffery et al., 2018).

Table 4.1.5.2. Genetic mixture analysis of Labrador subsistence fisheries for 2021 using the SNP range wide baseline (Jeffery et al., 2018). Mean percent values (and 95\% credible interval) by range wide reporting groups (Figure 4.1.5.1 and Figure 4.1.5.2) by size ( Small $<63 \mathrm{~cm}$, Large $>=63 \mathrm{~cm} ; 29$ samples did not have size data) and SFA. Reporting groups with zero support have been excluded from the table. Note that credible intervals with a lower bound including zero indicate little support for the mean assignment value.

Table 4.1.5.4. Genetic mixture analysis of Saint Pierre and Miquelon for 2020 to 2022 using the SNP range wide baseline (Jeffery et al., 2018). Mean percent values (and 95\% credible interval) by range wide reporting groups (Figure 4.1.5.1 and Figure 4.1.5.2) by size ( $\mathrm{Small}<63 \mathrm{~cm}$, Large >=63 cm ). Reporting groups with zero support have been excluded from the table. Note that credible intervals with a lower bound including zero indicate little support for the mean assignment value.

†: In 2020, some regions were affected by the COVID-19 global pandemic and monitoring programs could not operate. For this area previous 5-year average were used.

Table 4.3.2.2. Estimated large salmon returns (medians, 5th percentile, 95th percentile; X 1000) to the six geographic areas and overall, for NAC 1970 to $\mathbf{2 0 2 2}$. Returns for Scotia-Fundy (SF) do not include those from SFA 22 and a portion of SFA 23.

$\dagger$ : In 2020, some regions were affected by the COVID-19 global pandemic and monitoring programs could not operate. For this area previous 5-year average were used.

Table 4.3.2.3. Estimated 2SW salmon returns (medians, 5th percentile, 95th percentile; X 1000) to the six geographic areas and overall, for NAC 1970 to 2022. Returns for Scotia-Fundy (SF) do not include those from SFA 22 and a portion of SFA 23.

†: In 2020, some regions were affected by the COVID-19 global pandemic and monitoring programs could not operate. For this area previous 5-year average were used.
Table 4.3.3.2. Estimated large salmon spawners (medians, 5th percentile, 95th percentile; X 1000) to the six geographic areas and overall, for NAC 1970 to 2022. Spawners for Scotia-Fundy (SF) do not include those from SFA 22 and a portion of SFA 23.

$\dagger$ : In 2020, some regions were affected by the COVID-19 global pandemic and monitoring programs could not operate. For this area previous 5 -year average were used.

Table 4.3.3.3. Estimated 2SW salmon spawners (medians, 5th percentile, 95th percentile; X 1000) to the six geographic areas and overall, for NAC 1970 to 2022. Spawners for Scotia-Fundy (SF) do not include those from SFA 22 and a portion of SFA 23.

Table 4.3.4.1. Time-series of stocks in Canada and the USA with established CLs the number of rivers assessed and the number and percent of assessed rivers meeting CLs 1991 to 2022. In 2016, Quebec implemented a new Atlantic salmon management plan which changed their river-specific LRP values (Dionne et al., 2015) and DFO Gulf Region revised the river-specific reference points in 2018 (DFO 2018).

Table 4.3.5.4. Return rates (\%) by year of smolt migration of hatchery Atlantic salmon to 2 SW salmon to North American rivers 1991 to 2020 smolt migration years. The year 1991 was selected for illustration as it is the first year of the commercial fishery moratorium for Newfoundland.

Table 4.3.6.1. Estimates (medians, 5th percentiles, 95th percentiles; X 1000) of Pre-fishery Abundance (PFA) for 1SW maturing salmon (PFA1SWmat), 1SW non-maturing salmon (PFA1SWnmat) and the total cohort of 1SW salmon (PFA1SWcohort) as of 1 August of the second summer at sea for NAC for the years of Pre-fishery Abundance 1971 to 2022.

| Year | Median of estimated PFA ( $\mathrm{X} \mathbf{1 0 0 0 )}$ |  |  | 5th percentile of estimated PFA ( ${ }^{\text {1000 }}$ ) |  |  | 95th percentile of estimated PFA ( X 1000 ) |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | PFA1SWcohort | PFA1SWnmat | PFA1SWmat | PFA1SWcohort | PFA1SWnmat | PFA1SWmat | PFA1SWcohort | PFA1SWnmat | PFA1SWmat |
| 1971 | 1239.2 | 702.6 | 535.6 | 1170.1 | 639.9 | 500.6 | 1309.2 | 766.7 | 575.9 |

Figure 4.1.2.1. Map of Salmon Fishing Areas (SFAs) and Quebec Management Zones (Qs) in Canada.

Figure 4.1.2.2. Summary of recreational fisheries management measures in Canada in 2022. Note: details on specific regions are available in the text and may not appear on the figure.

Figure 4.1.3.1. Nominal catch (harvest; t) of small salmon, large salmon and both sizes combined (weight and number) for Canada, 1960 to 2022 (top panel) and 2008 to 2022 (bottom panel) by all users.

Figure 4.1.3.2. Nominal catch (harvest; number) of small salmon, large salmon, and both sizes combined in the recreational fisheries in Canada, 1974 to 2022 (top panel) and 2008 to 2022 (bottom panel).

Figure 4.1.3.3. The number (bars) of caught and released small salmon and large salmon in the recreational fisheries of Canada, 1984 to 2022. Black lines represent the proportion released of the total catch (released and retained) (grey diamond); small salmon (yellow circle) and large salmon (grey square).

(B)

Figure 4.1.4.1. Estimates of 2 SW salmon harvest equivalents (number of fish; year of $\mathbf{2 S W}$ harvests) taken at Greenland (year - 1) and in North America (upper panel A) and the percentages of the North American origin 2SW salmon harvest equivalents taken in various fishing areas of the North Atlantic (lower panel B) 1972 to 2022.

Figure 4.1.5.1 Map of North American sample locations used in the development of the SNP range wide baseline for Atlantic salmon (Jeffery et al., 2018). The 21 North American reporting groups are labelled and identified by colour). See Figure 4.1.5.2 for full range wide baseline sampling locations.

Figure 4.1.5.2. Map of range wide sample locations used in the development SNP baseline for Atlantic salmon and the $\mathbf{3 1}$ defined reporting groups (labelled and identified by colour) (Jeffery et al., 2018). See Figure 4.1.5.1 for finer resolution of North American locations.

Figure 4.1.5.3. Total tissue samples available and proportions of samples genotyped by Salmon Fishing Area in the Labrador Atlantic salmon subsistence fisheries in 2021 and 2022.

Region assignmen

Figure 4.1.5.4. Bayesian estimate of mixture composition of samples from the Labrador Atlantic salmon subsistence fisheries for 2021 by size group (small $<63 \mathrm{~cm}$, large $\geq 63 \mathrm{~cm}$ ) and region (Figure 4.1.2.1: SFA 1A - N. Labrador, SFA 1B - Lake Melville, and SFA 2 -S. Labrador) using the SNP range wide baseline for Atlantic salmon (Jeffery et al. 2018). Baseline locations refer to regional reporting groups identified in Figure 4.1.5.1 and Figure 4.1.5.2. Regional assignment acronyms are explained in Table 4.1.5.1. Data are summarized in Table 4.1.5.2. Note that credible intervals with a lower bound including zero indicate little support for the mean assignment value.

Region assignment

Figure 4.1.5.5. Bayesian estimate of mixture composition of samples from the Labrador Atlantic salmon subsistence fisheries for 2022 by size group (small $<63 \mathrm{~cm}$, large $\geq 63 \mathrm{~cm}$ ) and region (Figure 4.1.2.1: SFA 1A - N. Labrador, SFA 1B - Lake Melville, and SFA 2 -S. Labrador) using the SNP range wide baseline for Atlantic salmon (Jeffery et al. 2018). Baseline locations refer to regional reporting groups identified in Figure 4.1.5.1 and Figure 4.1.5.2. Regional assign-ment acronyms are explained in Table 4.1.5.1. Data are summarized in Table 4.1.5.3. Note that credible intervals with a lower bound including zero indicate little support for the mean assignment value.

Figure 4.1.5.6. Bayesian estimate of mixture composition of samples from the Saint Pierre and Miquelon Atlantic salmon fishery for 2020 by size group (small $<63 \mathrm{~cm}$, large $\geq 63 \mathrm{~cm}$ ) using the SNP range wide baseline for Atlantic salmon (Jeffery et al. 2018). Baseline locations refer to regional reporting groups identified in Figure 4.1.5.1 and Figure 4.1.5.2. Regional assignment acronyms are explained in Table 4.1.5.1. Data are summarized in Table 4.1.5.4. Note that credible intervals with a lower bound including zero indicate little support for the mean assignment value.

Figure 4.1.5.7. Bayesian estimate of mixture composition of samples from the Saint Pierre and Miquelon Atlantic salmon fishery for 2021 by size group (small $<63 \mathrm{~cm}$, large $\geq 63 \mathrm{~cm}$ ) using the SNP range wide baseline for Atlantic salmon (Jeffery et al. 2018). Baseline locations refer to regional reporting groups identified in Figure 4.1.5.1 and Figure 4.1.5.2. Regional assignment acronyms are explained in Table 4.1.5.1. Data are summarized in Table 4.1.5.4 Note that credible intervals with a lower bound including zero indicate little support for the mean assignment value.

Figure 4.1.5.8. Bayesian estimate of mixture composition of samples from the Saint Pierre and Miquelon Atlantic salmon fishery for 2022 by size group (small $<63 \mathrm{~cm}$, large $\geq 63 \mathrm{~cm}$ ) using the SNP range wide baseline for Atlantic salmon (Jeffery et al. 2018). Baseline locations refer to regional reporting groups identified in Figure 4.1.5.1 and Figure 4.1.5.2. Regional assignment acronyms are explained in Table 4.1.5.1. Data are summarized in Table 4.1.5.4. Note that credible intervals with a lower bound including zero indicate little support for the mean assignment value.

Figure 4.1.6.1. Exploitation rates in North America on the North American stock complex of small and large salmon 1971 to 2022. The symbols are the median and the error bars are the 5th to 95 th percentiles of the distributions from Monte Carlo simulation.

Figure 4.3.1.1. Time-series of wild smolt production from thirteen monitored rivers in eastern Canada and one river in eastern USA, 1970 to 2022. Smolt production is expressed as a proportion of the conservation egg requirements for the river. Note y-axis range change for the St Jean River, de la Trinité River and Vieux-Fort River relative to other rivers.

Figure 4.3.2.1. Total returns of small salmon (left column) and large salmon (right column) to English River (SFA 1), Southwest Brook (Paradise River) (SFA 2), Muddy Bay Brook (SFA 2), and Sand Hill River (SFA 2) Labrador, 1994-2022. The black triangle represents the previous generation mean and the blue circle represents the previous three generation mean. The data point with error bars for Sand Hill River in 2022 shows the estimated number of salmon if adjusted due to the delayed start of the monitoring program.

Figure 4.3.2.2. Estimated (median 5th to 95th percentile range, X 1000) returns (shaded circles) and spawners (open squares) of small salmon for NAC and to each of the six assessment regions 1971 to 2022. Returns and spawners for Scotia-Fundy do not include those from SFA 22 and a portion of SFA 23.

Figure 4.3.2.3. Estimated (median 5th to 95th percentile range, X 1000) returns (shaded circles) and spawners (open squares) of large salmon for NAC and to each of the six assessment regions 1971 to 2022. Returns and spawners for Scotia-Fundy do not include those from SFA 22 and a portion of SFA 23. For USA, estimated spawners exceed the estimated returns due to adult stocking restoration efforts.

Figure 4.3.2.4. Estimated (median 5th to 95th percentile range, X 1000) returns (shaded circles) and spawners (open squares) of 2SW salmon for NAC and to each of the six assessment regions 1971 to 2022. The dashed line is the corresponding 2SW Conservation Limit for NAC overall and for each region; the 2SW CL for USA (29 990 fish) is off the scale in the plot for USA. For Quebec, 2SW Conservation Limit correspond to the Upper Stock Reference point. The dotted line in the Scotia-Fundy and USA panels are the region-specific management objectives. Returns and spawners for Scotia-Fundy do not include those from SFA 22 and a portion of SFA 23. For USA, estimated spawners exceed the estimated returns in the later years due to adult stocking restoration efforts; therefore, 2SW returns are assessed relative to the management objective for USA.

Figure 4.3.2.5. Estimated (median, $X$ 1000) returns of small salmon to subregions of Newfoundland (SFA locations are shown in Figure 4.1.2.1) over the period 1971 to 2022. The exponential trend line and the percent change over the timeseries are shown in each panel.

Figure 4.3.4.1. Proportion of the conservation requirement attained in the 79 assessed rivers in 2021 (left panel) and the 80 assessed rivers in 2022 (right panel) of the North American Commission area

Figure 4.3.4.2. Time-series for Canada and the USA showing the number of rivers with established CLs, the number rivers assessed, and the number of assessed rivers meeting CLs for the period 1991 to 2022.

Figure 4.3.5.1. Estimated annual return rates (left and third column of panels; individual rivers are shown with different symbols and colours) and least squared (or marginal mean) mean annual return rates (with one standard error bars) (second and right column of panels) of wild origin smolts to 1 SW and 2 SW salmon to the geographic areas of North America. The standardized values are annual means derived from a general linear model analysis of rivers in a region. Note $y$-scale differences among panels. Standardized rates are not shown for regions with a single population.

Figure 4.3.5.2. Estimated annual return rates (left and third column of panels; individual rivers are shown with different symbols and colours) and least squared (or marginal mean) mean annual return rates (with one standard error bars) of hatchery origin smolts to 1 SW and 2 SW salmon to the geographic areas of North America. The standardized values are annual means derived from a general linear model analysis of rivers in a region. Note yscale differences among panels. Standardized rates are not shown for regions with a single population.

Figure 4.3.6.1. Estimated (median, 5th to 95th percentile range, X 1000) Pre-fishery Abundance (PFA) for 1SW maturing, 1SW non-maturing, and total cohort of 1SW salmon for NAC, PFA years 1971 to 2022. The dashed blue horizontal line is the corresponding sum of the 2SW conservation limits for NAC ( 143494 ) corrected for 11 months of natural mortality (193 697) against which 1SW non-maturing are assessed.

Figure 4.3.7.1. Estimated returns (circle symbol) and spawners (square symbol) of 2 SW salmon in 2021 to six assessment regions of North America relative to ICES stock status categories. The percentage of the 2SW CLs for the four northern regions and to the rebuilding management objectives (MO) for the two southern areas are shown based on the median of the Monte Carlo distribution. For Quebec, 2SW CL correspond to the Upper Stock Reference point. The colour shading is interpreted as follows: blue refers to the stock being at full reproductive capacity (median and 5th percentile of the Monte Carlo distributions are above the CL ), orange refers to the stock being at risk of suffering reduced reproductive capacity (median is above but the 5th percentile is below the CL), and red refers to the stock suffering reduced reproductive capacity (the median is below the CL).

Figure 4.3.7.2. Estimated returns (circle symbol) and spawners (square symbol) of 2 SW salmon in 2022 to six assessment regions of North America relative to ICES stock status categories. The percentage of the 2SW CLs for the four northern regions and to the rebuilding management objectives (MO) for the two southern areas are shown based on the median of the Monte Carlo distribution. For Quebec, 2SW CL correspond to the Upper Stock Reference point. The colour shading is interpreted as follows: blue refers to the stock being at full reproductive capacity (median and 5th percentile of the Monte Carlo distributions are above the CL ), orange refers to the stock being at risk of suffering reduced reproductive capacity (median is above but the 5th percentile is below the CL ), and red refers to the stock suffering reduced reproductive capacity (the median is below the CL ).

## 5 Atlantic salmon in the West Greenland Commission

### 5.1 NASCO has requested ICES to describe the key events of the $\mathbf{2 0 2 1}$ and $\mathbf{2 0 2 2}$ fisheries

The Atlantic salmon fishery is regulated according to the Government of Greenland's Executive Order no. 29 of 28 July 2022. Since 1998, with the exception of 2001, the export of Atlantic salmon has been banned. There are two landing categories reported for the fishery: commercial landings where professional licensed fishers can sell salmon to hotels, institutions and local markets and recreational landings where both professional fishers and non-professional fishers fish for private consumption. Since 2018, all fishers are required to have a license to fish for Atlantic salmon.

In 2021, the Government of Greenland published a "Management Plan for Atlantic Salmon in Greenland" (GoG 2021), which is to remain in force from July 1, 2021 through December 31, 2025. The management plan recognizes three separate management areas and specifies fishing seasons for each. The plan also outlines two different users groups and outlines how established total allowable catches (TAC) will be distributed according to historical catch data. The purpose of the management plan is to ensure access for the Greenlandic population to the utilization of Atlantic salmon while taking into account the international agreements that Greenland has negotiated.

| Management Areas | Fishing season | User Group | \% of TAC by area | \% of TAC by user group |
| :--- | :--- | :--- | :--- | :--- |
| Northwest | 01 Sep - 31 Oct |  | $40 \%$ |  |
|  |  | Commercial | $28 \%$ |  |
| Southwest | Recreational |  | $12 \%$ |  |
|  |  |  | $60 \%$ | $42 \%$ |
| East Greenland |  | Recreational |  | $18 \%$ |
|  |  |  |  |  |

In 2021, parties of the West Greenland Commission of NASCO could not agree to a multiyear regulatory measure and instead agreed to an "Interim Regulatory Measure for Fishing for Atlantic Salmon at West Greenland in 2021" (NASCO 2021; see WGC(21)18). The interim agreement maintained many of the provisions that were in the preceding measures such as a continuation of a ban on the export of wild Atlantic salmon, restricting the fishery to August through November, requiring all fishers to have a license, requiring fishers to allow samplers access to their catch and requiring fishers to report their catch, even zero harvest. As outlined in the measure, the Government of Greenland set a total quota for all components of the 2021 fishery at West Greenland to 27 t .

In 2022, parties of the West Greenland Commission of NASCO were able to agree to a "MultiAnnual Regulatory Measure for Fishing for Atlantic Salmon at West Greenland" to cover the time period of 2022-2025 (NASCO 2022; see WGC(22)10). The agreement also maintained many
of the provisions that were in the preceding measures while also outlining a new measure to minimize the likelihood of overharvest. At least for the first year of the agreement, it was agreed that the fishery would be closed when the registered catch had reached no more than $49 \%$ of the overall TAC to help ensure that the TAC would not be exceeded. In subsequent years, the percentage could be adjusted, in consultation with the Commission, based on previous experiences and the expected effect of new management measures. As outlined in the measure, the Government of Greenland set a total quota for all components of the 2022 fishery at West Greenland to 27 t .

The total catch was first reported to NASCO as $41 \mathrm{t}(40 \mathrm{t}$ at West Greenland and 1 t at East Greenland) for the 2021 fishery and 28 t ( 28 t at West Greenland and $<1 \mathrm{t}$ at East Greenland) for the 2022 fishery. Detailed statistics on the opening and closing dates, quotas and quota uptake by each region and user group are provided below.

| Management Areas | Opening Dates | User Groups | $\begin{aligned} & \text { 2021/2022 } \\ & \text { Quotas ( } \mathrm{t} \text { ) } \end{aligned}$ | 2021 Closing <br> Dates | $\begin{aligned} & 2021 \\ & \text { Catch (t) } \end{aligned}$ | 2022 Closing <br> Dates | 2022 Catch <br> (t) |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Northwest | 01 Sep |  |  |  |  |  |  |
|  |  | Commercial | 7.56 | 22 Sep | 15.86 | 19 Oct | 8.62 |
|  |  | Recreational | 3.24 | 01 Oct | 3.26 | 31 Oct | 1.49 |
| Southwest | 01 Aug |  |  |  |  |  |  |
|  |  | Commercial | 11.34 | 15 Sep | 14.95 | 22 Aug | 11.23 |
|  |  | Recreational | 4.86 | 22 Sep | 5.90 | 11 Sep | 6.36 |
| East Greenland | 15 Aug |  |  |  |  |  |  |
|  |  | Commercial | 1.5 | 15 Oct | 0.45 | 15 Oct | 0.27 |
|  |  | Recreational | 1.5 | 15 Oct | 0.56 | 15 Oct | 0.36 |

Updated catch figures for 2021 and 2022 have since been reported to ICES resulting in small increases in the total landings (increase of 2.24 t in 2021 and 1.46 t in 2022). The updated catch totals are reported in the following sections and used for assessment purposes.

### 5.1.1 Catch and effort in 2021 and 2022

Only hooks, fixed gillnets and driftnets are allowed to target salmon directly and the minimum mesh size has been 140 mm (stretched mesh) since 1985. Commercial fishers are allowed to use up to 20 gillnets at a time either as single gillnets fixed to the shore or up to 20 sections ( $\sim 70 \mathrm{~m}$ per section) connected and used as a driftnet. Recreational licensed fishers can only use one gillnet fixed to the shore or rod and reel. All nets must be tended regularly and marked with name and contact information. Gillnets are only allowed in the inshore areas.

Nets are the preferred gear in Greenland and very little rod and reel fishing in salt water takes place. However, a small recreational fishery directly targeting salmon via rod and reel has been noted in the Nuuk and Qaqortoq regions. Reports from recreational fishers fishing with rod and reel are received annually and are included in the reported landings. Landings from this gear type are considered insignificant at this time.

As in past years, Officers from the Greenland Fisheries License Control Authority (GFLK) have patrolled areas with known salmon fishing activity during and after the season to remove gillnets if they lack name information or are not set in accordance with regulations. In 2022, two untended gillnets were removed by GFLK just south of Nuuk. Officers also continue to visit local markets and public institutions to maintain a presence at these locations and to encourage adherence to the fishing regulations.

Catch data were collated from fisher reports. The reports were screened for errors and missing values. Catches were assigned to a NAFO/ICES Division based on the reporting community. Reports which contained only the total number of salmon caught or the total catch weight without the number of salmon, were corrected using 3.25 kg gutted weight per salmon. Since 2005, it has been mandatory to report gutted weights, and these have been converted to whole weight using a conversion multiplier of 1.11. It was noted that errors in reported catch data have been decreasing given improved catch reporting since 2018, given the mandatory requirement for all fishers to report catches.

The total updated catch figures are 43.2 t ( 41.8 t for West Greenland and 1.4 t for East Greenland) for 2021 and 29.8 t ( 29.0 t for West Greenland and 0.8 t for East Greenland) for 2022 (Table 5.1.1.1). Reported catch was distributed among the six NAFO Divisions on the west coast of Greenland and in ICES Division XIV on the east coast of Greenland (Table 5.1.1.2; Figure 5.1.1.1). The 2021 reported landings is the highest value since 2015 while the 2022 value is a decrease of over 13 t from the 2021 value. Harvest reported for East Greenland is not included in assessments of the contributing stock complexes, owing to a lack of information on the stock composition of that fishery. Reported landings of Atlantic salmon increased from 60 t in 1960 to a peak of 2689 t reported in 1971 and generally decreased until the closure of the export commercial fishery in 1998. Reported landings for the internal use only fishery peaked at 57.9 t in 2014 and have averaged 39.2 t over the past ten years (2013-2022; Table 5.1.1.1; Figure 5.1.1.2). The majority of the catch in 2021 and 2022 was reported by commercial fishers as in previous years (Figure 5.1.1.2).

| Reported Landings |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Reported Landings (t (\%)) |  |  |  | Landings Type (t (\%)) |  |
|  | West Greenland only | East Greenland | Total | Commercial | Recreational |
| 2022 | 30.9 (97.5\%) | 0.8 (2.5\%) | 31.7 | 20.6 (69.3\%) | 9.2 (30.7\%) |
| 2021 | 41.8 (96.8\%) | 1.4 (3.2\%) | 43.2 | 32.2 (74.6\%) | 11.0 (25.4\%) |
| 2020 | 29.0 (97.3\%) | 0.8 (2.7\%) | 29.8 | 22.0 (69.5\%) | 9.7 (30.5\%) |

There is currently no quantitative approach for estimating the unreported catch for the fishery, but the 2022 value is likely to have been at the same level as reported by the Greenlandic authorities in recent years ( 10 t ). The 10 t estimate was historically meant to account for recreational fishers in smaller communities fishing for recreational use, but not reporting landings. This estimate was not meant to represent non-reporting by commercial fishers.

The Working Group has employed two different approaches to estimate unreported catch from commercial fishers: comparisons of the sampling programme statistics and reported landings and utilizing results from the previously implemented phone surveys. The need for an adjustment for some unreported catch, primarily for commercial landings, has been assessed annually since 2002 by comparing the weight of salmon seen by the sampling teams and the corresponding community-specific reported landings for the entire fishing season (see Section 5.2). However, sampling only occurs during a portion of the fishing season and therefore these adjustments are considered minimum unreported catch adjustments.

The seasonal distribution of catches has previously been reported to the Working Group (ICES, 2002), but since 2002 this has generally not been possible. Although fishers are required to record daily catches, previous comparisons of returned catch reports suggest that many fishers do not
provide daily statistics. The seasonal distribution for factory landings, when allowed, is assumed to be accurate given the reporting structure in place between the factories and the GFLK.

Greenland Authorities issued 939 licences ( 360 for commercial fishers and 579 for recreational fishers) and received 1840 reports from 671 fishers in 2021 and issued 757 licences ( 291 for commercial fishers and 466 for recreational fishers) and received 1266 reports from 504 fishers in 2022 (Tables 5.1.1.3 and 5.1.1.4; Figure 5.1.1.3). The number of licences issued, the number of fishers who reported, and the number of reports received have increased greatly since 2017 as a result of the new regulations requiring all fishers to receive a licence and mandatory reporting requirements. The levels are among the highest in the time-series and the number of fishers reporting landings matches the levels recorded during the commercial export fishery from 1987 to 1991. The number of licences issued and the number of fishers who reported catches in 2021 were the highest level recorded, but both decreased in 2022. The percentage of fishers that reported catches peaked in 2019 at $91 \%$ for commercial and $87 \%$ for recreational, but has decreased each year since with $68 \%$ of commercial fishers reporting catches and $67 \%$ of recreational fishers in 2022.

| Licenses and Reporting |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Licenses Issued |  |  | Number of Fishers Reporting (\%) |  |  |
|  | Commercial | Recr | Total | Commercial | Recreational | Total |
| 2022 | 339 | 418 | 757 | 277 (82\%) | 341 (82\%) | 618 (82\%) |
| 2021 | 360 | 579 | 939 | 281 (78\%) | 424 (73\%) | 668 (71\%) |
| 2020 | 291 | 466 | 757 | 199 (68\%) | 312 (67\%) | 511 (68\%) |

The Working Group previously reported on the procedures for reporting salmon harvested in Greenland (ICES, 2014; ICES, 2016) and modifications to these procedures were made by the Government of Greenland in 2018. In summary, all fishers are required to have a licence to fish for Atlantic salmon and all licence holders are required to report catches. Reports can be made to GFLK by e-mail, phone, fax, or return logbook on a daily basis. Factory landings, when allowed, are submitted to GFLK either on a daily or weekly basis, depending on the likelihood of exceeding a quota. No factory landings have been allowed since 2015.

### 5.1.2 Phone surveys

Phone surveys were conducted in 2015, 2016, and 2017 to assess the 2014, 2015, and 2016 fisheries, respectively. The number of fishers contacted, the questions asked, and the method to estimate unreported catch differed from year to year. Based on the results from these surveys, estimated 'adjusted landings (survey)' of 12.2 t for the 2014 fishery, 5.0 t for the 2015 fishery, and 4.2 t for the 2016 fishery were added to the 'adjusted landings (sampling)' as described in Section 5.2, and 'reported landings' to estimate the 'landings for assessment'. A phone survey was initiated for the 2017 fishery, but only nine fishers were contacted and no landings adjustment were estimated. Phone surveys have not been conducted since the 2017 fishery and therefore no landing adjustments have been estimated since that time. A summary of the reported landings, adjusted landings (sampling), and adjusted landings (survey) is presented in Table 5.1.2.1. Adjusted 'landings for assessment' do not replace the official reported statistics.

### 5.1.3 Exploitation

An extant exploitation rate for NAC and Southern NEAC non-maturing 1SW fish at West Greenland can be calculated by dividing the estimated continent of origin reported harvest of 1SW
salmon at West Greenland by the PFA estimate for the corresponding year for each stock complex. Exploitation rates are available for the 1971 to 2021 PFA years (Figure 5.1.3.1). The most recent estimate of exploitation available is for the 2021 fishery as the 2022 exploitation rate estimates are dependent on the 2022 PFA estimates derived from 2023 2SW returns. NAC PFA estimates (Table 4.3.6.1) are provided for August of the PFA year and Southern NEAC PFA estimates (Table 3.3.4.4) are provided for January of the PFA year, the latter adjusted by seven months (1 January to 1 August) of natural mortality at 0.03 per month. The 2020 and 2021 NAC exploitation rates were $4.8 \%$ and $6.7 \%$ respectively. These values are in line with the mean estimate ( $7.0 \%$ ) for the 2002-2021 time period and remain among the lowest in the time-series. NAC exploitation rate peaked in 1971 at approximately $40 \%$. The 2020 and 2021 Southern NEAC exploitation rates were $1.4 \%$ and $0.5 \%$ respectively. The 2020 estimate was a doubling from the previous three years, but the 2021 value decreased back to the mean estimate ( $0.6 \%$ ) for the 2002-2021 time period. Southern NEAC exploitation rate at Greenland peaked in 1975 at $33 \%$. It should be noted that annual estimates of exploitation vary slightly from year to year as they are dependent on the output from the run-reconstruction models, which vary slightly from assessment to assessment (see Sections 4.3.6 and 3.3.1).

### 5.2 International sampling programme

Although some results from the 2020 International Sampling Programme have previously been reported on (ICES 2021a), not all sample processing had been completed at that time. All sampling processing and analysis have since been finalized and these updated results are presented below and all tables and figures have been updated as appropriate. Care should be taken when interpreting results from the 2020 sampling as the overall sample size was relatively low given challenges associated with sampling the fishery during the COVID-19 pandemic (ICES 2021a).

The international sampling programme for the fishery at West Greenland agreed by the parties at NASCO continued in 2021 (NASCO 2021; see WGC(21)15). The sampling was undertaken by participants from France (1), Ireland (1), and UK (Northern Ireland; 1). Additional samplers from Canada (1), UK (England \& Wales; 1) and USA (1) were scheduled to participate, but travel restrictions associated with the COVID-19 pandemic prevented them from participating. To increase the sampling coverage, a local resident from Qaqortoq, Greenland was hired to provide sampling in that community throughout the fishing season. Samplers were stationed in three communities (Figure 5.1.1.1) representing three NAFO Divisions: Sisimiut (NAFO division 1B), Maniitsoq (1C), and Qaqortoq (1F). Samples were also collected in Nuuk (1D) by an employee of the Greenland Institute of Natural Resources (GINR). Sampling was conducted from August $2^{\text {nd }}$ through October 4 ${ }^{\text {th }}$ in 2021.

A Citizen Science Programme was also conducted in 2021 by the GINR. A Citizen Science Programme had been initiated in 2020 with limited success given unforeseen complication associated with the COVID-19 pandemic (ICES 2021a). The 2021 effort involved sending a mailing to all license holders who had reported catches of five or more salmon in 2020. The mailing contained a letter requesting the fishers help to collect biological characteristics data and scale and tissue samples from their catch, an instruction sheet and 5 scale envelopes. It was requested that any collected samples and data be returned to the GINR at the conclusion of the fishing season.

The international sampling programme for the fishery at West Greenland agreed by the parties at NASCO continued in 2022 (NASCO 2022; see WGC(22)10). The sampling was undertaken by participants from France (1), Ireland (1), UK (England \& Wales; 1) and USA (1). To increase the sampling coverage, a local resident from Qaqortoq, Greenland was again hired to provide sampling in that community throughout the fishing season. Samplers were set to be stationed in four communities (Figure 5.1.1.1) representing four NAFO Divisions: Sisimiut (NAFO division 1B),

Maniitsoq (1C), Paamiut (1E) and Qaqortoq (1F). However, one of the samplers was unable to travel from Nuuk to Paamiut given weather complications and instead collected samples from the local market in Nuuk. No additional samples were collected in Nuuk by the GINR and a Citizen Science Programme was not pursued. Sampling was conducted from August $1^{\text {st }}$ through September 15 th in 2022.

In 2020, a total of 197 salmon were sampled, which represents $1 \%$ of the reported landings. Samples were provided from three sources and originated from three NAFO Divisions. A total of 140 fork lengths, 44 weights, 76 scale samples for age determination and 197 tissue samples were collected (Table 5.2.1). As noted prior, sampling in 2020 was particularly challenging given the COVID-19 pandemic and the low samples size is reflective of that.

| 2020 | NAFO Division/ICES Statistical Area |  |  |  |  |  |
| :--- | :--- | :---: | :---: | :---: | :---: | :---: |
| Sample Source | 1 A | 1 B | 1 C | 1 D | 1 E | 1 F |
| Citizen Science |  | 18 | 10 | 3 | XIV | Total |
| GFLK | 9 | 6 | 11 | 31 |  |  |
| GINR | 140 |  |  | 26 |  |  |
| Total | 167 | 16 | 14 | 140 |  |  |

In 2021, a total of 1548 salmon were observed by the sampling teams, approximately $17 \%$ by weight of the reported landings. Samples were provided from three sources and originated from six NAFO Divisions and from ICES Statistical Area XIV. A total of 1293 fork lengths, 1184 weights, 1308 scale samples for age determination, and 1532 tissue samples were collected (Table 5.2.1).

| 2021 | NAFO Division/ICES Statistical Area |  |  |  |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Sample Source | 1 A | 1 B | 1 C | 1 D | 1 E | 1 F | XIV | Total |
| Citizen Science | 6 | 60 | 55 | 19 | 33 | 65 | 14 | 252 |
| GINR |  |  |  | 393 |  |  | 393 |  |
| Sampling Programme | 6 | 191 | 708 | 412 | 33 | 184 | 14 | 1548 |
| Total |  |  |  |  |  |  |  |  |

In 2022, a total of 1170 salmon were observed by the sampling teams, approximately $11 \%$ by weight of the reported landings. A total of 672 fork lengths, 672 weights, 631 scale samples for age determination, and 670 tissue samples were collected (Table 5.2.1).

| 2022 | NAFO Division/ICES Statistical Area |  |  |  |  |  |  |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Sample Source | 1 A | 1 B | 1 C | 1 D | 1 E | 1 F | XIV | Total |
| Sampling Programme | 29 | 308 | 282 | 31 | 22 | 672 |  |  |
| Total | 29 | 308 | 282 | 31 | 22 | 672 |  |  |

The International Sampling Programme has been successful at sampling the harvest of Atlantic salmon at Greenland annually and the data collected has contributed valuable inputs to the assessment models used by the Working Group. Prior to any sampling, the sampler always obtains permission from the market manager or fisher before sampling the catch. This arrangement has generally been successful for all samplers, although there have been a small number of issues in some years in some communities. In 2022 access to landed salmon was denied to the sampler in Qaqortoq after only a few days of sampling. Intervention by the Government of Greenland was initiated, but the situation was not remedied during the fishing season. Intervention continued after the fishing season and access is expected to be restored in 2023.
In 2021, six adipose fin clipped fish were recorded, no internal or external tags were identified by the samplers. In 2021, three tags were provided directly to the GINR (a PIT tag, an acoustic tag and a carlin tag). The carlin tag was from an adult fish tagged in the Margaree River (Canada) in 2020. In 2022, four adipose fin clipped fish were recorded and a single cwt tag was recovered and no other internal or external tags were identified by the samplers. The cwt tag is still being processed and the origins of the PIT and acoustic tag remain unknown.

Starting in 2002, non-reporting of harvest was evident based on a comparison of reported landings and sample data. When there is this type of discrepancy, the reported landings are adjusted ("Adjusted landings (sampling)") according to the estimated total weight of the fish identified as being landed during the sampling effort and these adjusted landings are carried forward for assessments. Adjusted landings do not replace the official reported statistics (Tables 5.1.1.1 and 5.1.1.2). Landings for assessment are presented in Table 5.1.2.1. No adjustments have been made since 2017 and details of all adjustments made to date have been reported previously (ICES 2021a).

### 5.2.1 Biological characteristics of the catches

In 2020, the mean length and whole weight of North American 1SW salmon were 66.6 cm and 3.20 kg and the means for European 1SW salmon were 65.6 cm and 3.38 kg . In 2021, the mean length and whole weight of North American 1SW salmon were 66.2 cm and 3.34 kg and the means for European 1SW salmon were 65.9 cm and 3.34 kg . In 2022, the mean length and whole weight of North American 1SW salmon were 63.9 cm and 2.79 kg and the means for European 1SW salmon were 62.4 cm and 2.73 kg . The 2020 values are similar to the 2021 values whereas the 2022 values decreased from the 2021 values and are all below the previous 10 -year means (2012-2021; Table 5.2.1.1). The mean length and weight data reported in Table 5.2.1.1 have not been adjusted for the period of sampling and it is known that salmon grow quickly during the period of feeding at West Greenland. Preliminary analyses to adjust for period of sampling have been previously reported (ICES 2011; ICES 2015) and therefore caution is urged when interpreting the uncorrected data.

North American salmon sampled from the fishery at West Greenland were predominantly river age two ( $28.2 \%, 27.3 \%$ and $24.9 \%$ ), three ( $23.1 \%, 38.3 \%$ and $38.7 \%$ ) and four ( $28.2 \%, 21.7 \%$ and $24.1 \%$ ) year old fish in 2020, 2021 and 2022 respectively (Table 5.2.1.2). European salmon were predominantly river age two ( $74.2 \%, 58.2 \%$ and $53,8 \%$ ) and three $(9.7 \%, 19.1 \%$ and $17.9 \%)$ year old fish in 2020, 2021 and 2022 respectively (Table 5.2.1.3). As expected, the 1SW age group dominated the sample collection for both the North American ( $92.3 \%, 95.5 \%$ and $94.7 \%$ ) and European ( $97.1 \%, 97.9 \%$ and $90.0 \%$ ) origin fish in 2020, 2021 and 2022 respectively (Table 5.2.1.4).

### 5.2.2 Continent and region of origin of catches at West Greenland

In 2020, 196 of 197 tissue samples collected from three NAFO Divisions were genetically analysed: 1B $(\mathrm{n}=167)$, 1E $(\mathrm{n}=16)$ and 1F $(\mathrm{n}=13$; Figure 5.2.2.1). In 2021, 1518 of 1532 tissue samples collected from six NAFO Divisions and from ICES Statistical Area XIV were genetically analysed: $1 \mathrm{~A}(\mathrm{n}=6), 1 \mathrm{~B}(\mathrm{n}=187), 1 \mathrm{C}(\mathrm{n}=702), 1 \mathrm{D}(\mathrm{n}=408), 1 \mathrm{E}(\mathrm{n}=33) 1 \mathrm{~F}(\mathrm{n}=182)$ and XIV (n=14; Figure 5.2.2.2). In 2022, 669 of 670 tissue samples collected from five NAFO Divisions were genetically analysed: $1 \mathrm{~B}(\mathrm{n}=29), 1 \mathrm{C}(\mathrm{n}=307), 1 \mathrm{D}(\mathrm{n}=280), 1 \mathrm{E}(\mathrm{n}=31)$ and $1 \mathrm{~F}(\mathrm{n}=22$; Figure 5.2.2.3 $)$.

Since 2017, a Single Nucleotide Polymorphism (SNP) rangewide baseline (Jeffery et al., 2018) providing 21 North American and ten European reporting groups has been used for continent and region of origin analysis. The baseline has been revised, resulting in 21 North American and ten European reporting groups (Table 5.2.2.1 and Figure 5.2.2.4; ICES 2019a). A Bayesian approach is used to estimate mixture composition or assign individuals to continent and region of origin. The approach uses the R package rubias (Anderson et al., 2008).

In 2020, $55.6 \%$ of the salmon sampled were of North American origin and $44.4 \%$ were of European origin (Table 5.2.2.2). In 2021, samples collected from West Greenland were $82.3 \%$ North American origin and $17.7 \%$ European origin (Table 5.2.2.3). Samples collected from East Greenland (ICES Statistical Area XIV) were 71.4\% North American and 28.6\% European). These represent the first genetic samples analysed from the East Greenland fishery as previously analysed historical samples originated from research surveys (Bradbury et al. 2015). In 2022, 93.7\% of the salmon sampled were North American origin and $6.37 \%$ were European origin (Table 5.2.2.4). These findings show that large proportions of fish from the North American stock complex continue to contribute to the fishery (Table 5.2.2.5 and Figure 5.2.2.5). The proportion North American was fairly low in 2020, but sample size was also low and therefore the results may be skewed. The 2021 and 2022 values both increased from the 2020 value and the 2022 estimate is the highest proportion North American recorded in the time-series. The NAFO division-specific continent of origin assignments for 2001-2022 are presented in Figure 5.2.2.6. The annual variation in the continental representation among divisions within the recent time-series underscores the need to sample multiple NAFO Divisions to achieve the most accurate estimate of the contribution of fish from each continent to the mixed-stock fishery.

The estimated weighted proportions of North American and European salmon since 1982 and the weighted numbers of North American and European salmon caught at West Greenland (excluding unreported catch and reported harvest from ICES Statistical Area XIV) are provided in Table 5.2.2.5 and Figure 5.2.2.7. Approximately 5200 ( 17.2 t) North American origin fish and 3600 (13.7 t) European origin fish were harvested in 2020. Approximately 10300 (34.4 t) North American origin fish and $2000(7.4 \mathrm{t})$ European origin fish were harvested in 2021 and approximately $9200(27.2 \mathrm{t})$ North American origin fish and $900(1.8 \mathrm{t})$ European origin fish were harvested in 2022.

The Working Group has previously reported on the region of origin of catches at West Greenland, both for North American and European origin salmon (ICES, 2019). Region of origin estimates for the 2020-2022 fisheries, based on the updated rangewide SNP baseline, are provided in Tables 5.2.2.6, 5.2.2.7, 5.2.2.8 and Figures 5.2.2.8, 5.2.2.9, 5.2.2.10.

As in previous years, the North American contributions to the West Greenland fishery are dominated by the Gaspe Peninsula, the Gulf of St Lawrence, and the Labrador South reporting groups. These three groups accounted for $78 \%$ of the North American contributions in 2020, $88 \%$ in 2021 and $60 \%$ in 2022. The Northeast Atlantic contributions were dominated by the United Kingdom/Ireland reporting group ( $93 \%, 92 \%$ and $88 \%$ of the European contributions in 2020, 2021 and 2022 respectively). From North America, there are smaller, but consistent contributions to the harvest for a number of other reporting groups (e.g. Lake Melville, St. Lawrence North

Shore-Lower, Maine, United States, Labrador Central; Tables 5.2.2.6, 5.2.2.7, and 5.2.2.8 and Figures 5.2.2.8, 5.2.2.9 and 5.2.2.10). These results support the previous conclusion by ICES (2017) that stocks from Northern NEAC do not contribute a significant amount to the harvest at West Greenland. Further, the variation in NAFO division-specific region of origin assignments highlight the variation of region-specific contributions across years and NAFO divisions.

In 2022, a single sample collected from Nuuk (NAFO Division 1D) was identified as having originated from the Greenland (i.e. Kapisillit River) reporting group. This is the second time a sample has been assigned the Greenland reporting group. The first time was in 2018 and the sample originated from Maniitsoq (NAFO Division 1C). The SNP baseline, which includes the Greenland reporting group has only been in operation since 2017.

### 5.3 NASCO has requested ICES to describe the status of the stocks

The stocks contributing to the Greenland fishery are the NAC 2 SW and Southern NEAC MSW complexes. The midpoints of the spawner abundance estimates for four of the seven stock complexes exploited at West Greenland were below CLs in 2022 (Figure 5.3.1) . A more detailed overview of status of stocks in the NEAC and NAC areas is presented in the relevant Commission sections (Sections 3 and 4).

### 5.3.1 North American stock complex

The total estimate of 2SW salmon spawners in North America for 2022 increased in all areas ( $11 \%$ to $243 \%$ ) except for Newfoundland ( $-53 \%$ ) and were the $6^{\text {th }}$ highest on record (1971-2022; 52 years). The midpoints of the spawner abundance estimates were $158 \%$ of the 2SW CL for Labrador, $93 \%$ for Newfoundland, $72 \%$ for Quebec, $134 \%$ for Gulf, $8 \%$ for Scotia-Fundy and $5 \%$ for USA. The region is considered to be at full reproductive capacity, Labrador is considered to be at risk of suffering full reproductive capacity and Quebec, Newfoundland, Scotia-Fundy and USA are suffering reduced reproductive capacity (Figure 4.3.7.1b). Scotia-Fundy and USA met $19 \%$ and $33 \%$ of their Management Objective in 2022 respectively. Within each of the geographic areas, there are individual river stocks which are failing to meet CLs (Table 4.3.4.1 and Figures 4.3.4.1 and 4.3.4.2). In the southern areas of NAC (Scotia-Fundy and USA) there are numerous populations at high risk of extinction and these are under consideration or receiving special protections under federal legislation. The estimated exploitation rate of salmon in North American fisheries has declined (Figure 4.1.6.1) from a peak of $81 \%$ in 1971 for 2 SW salmon to a mean of $9 \%$ over the past ten years.

### 5.3.2 MSW Southern European stock complex

The midpoint of the spawner abundance estimate for the Southern NEAC MSW stock complex was above the CL and is therefore is at full reproductive capacity (Figure 3.3.4.2). Individual countries stock status within the NEAC MSW stock complex varied across all three stock status designations (Figure 3.3.4.5). Note that rivers in the south and west of Iceland are included in the assessment of the Southern NEAC stock complex. Within individual jurisdictions, there are large numbers of rivers not meeting CLs after homewater fisheries (Table 3.3.5.1 and Figure 3.3.5.1). Homewater exploitation rates on the MSW Southern NEAC stock complex are shown in Figure 3.1.9.1. Exploitation on MSW fish in Southern NEAC was 3\% in 2021 and 2022, which was lower than the previous five year ( $4 \%$ ) and ten year ( $5 \%$ ) means.

Table 5.1.1.1. Nominal catches of salmon at West Greenland since 1960 ( t round fresh weight) by participating nations. For Greenlandic vessels specifically, all catches up to 1968 were taken with set gillnets only and catches after 1968 were taken with set gillnets and driftnets. All non-Greenlandic vessel catches from 1969-1975 were taken with driftnets. The quota figures applied to Greenlandic vessels only and parenthetical entries identify when quotas did not apply to all sectors of the fishery.

| Year | Norway | Faroes | Sweden | Denmark | Greenland | Total | Quota | Comments |

1 The fishery was suspended.

+ Small catches $<\mathbf{5}$ t.
- No catch.

Table 5.1.1.3. Total number of licences issued and number of fishers reporting catches of Atlantic salmon in the Greenland fishery by NAFO (1A-1F)/ICES divisions. Reports received by fish factories prior to 1997 and to the Licence Office from 1998 to present. Blanks cells indicate that the data were not reported or available. Starting in 2018, a new regulation was enacted which required all fishers to have a licence to fish for Atlantic salmon. Prior to 2018, only commercial fishers were required to have a licence.

Table 5.1.2.1. Adjusted landings estimated from comparing the weight of salmon seen by the sampling teams and the corresponding community-specific reported landings (Adjusted landings (sampling)) and from phone surveys (Adjusted landings (survey)). Dashes '-' indicate that no adjustment was necessary or that a phone surveys was not conducted. Adjusted landings (sampling and surveys) are added to the reported landings for assessment purposes. Adjusted landings do not replace official reported statistics. Rounding issues are evident for some totals.

Table 5.2.1. Size of biological samples and percentage (by number) of North American and European salmon in research vessel catches at West Greenland (1969 to 1982), from commercial samples (1978 to 1992, 1995 to 1997, and 2001) and from local consumption samples (1998 to 2000, and 2002 to present). Parenthetical sample numbers represent the number of samples available. Genetic-based continent of origin assignments are considered to be $\mathbf{1 0 0 \%}$ accurate.

${ }^{1}$ CI - confidence interval calculated by method of Pella and Robertson (1979) for 1984-1986 and binomial distribution for the others.
${ }^{2}$ During 1978 Fishery.
${ }^{3}$ Research samples after 1978 fishery closed.

Table 5.2.1.1. Annual mean whole weights ( kg ) and fork lengths ( cm ) by sea age and continent of origin of Atlantic salmon caught at West Greenland 1969 to the present, excluding 1977, 1993 and 1994 (NA = North America and E = Europe). These data have not been adjusted for the period of sampling and it is known that salmon grow quickly during the period of feeding at West Greenland. Caution is urged when interpreting these uncorrected data. In addition, some estimates, especially with the older sea age fish are based on a small number of samples.

Table 5.2.2.6. Bayesian estimates of mixture composition for West Greenland Atlantic Salmon fishery by region and overall for 2020. Baseline locations refer to regional reporting groups identified in Table 5.2.2.1 and Figure 5.2.2.4. Sample locations are identified by NAFO Divisions. Mean estimates provided with $95 \%$ credible interval in parentheses. Estimates of mixture contributions not supported by significant individual assignments ( $\mathrm{P}>0.8$ ) are represented as zero and
therefore all columns may not add up to 100. Credible intervals with a lower bound of zero, or close to zero, may indicate little support for the mean assignment value.

Table 5.2.2.7 Bayesian estimates of mixture composition for West Greenland Atlantic Salmon fishery by region and overall for 2021. Baseline locations refer to regional reporting groups identified in Table 5.2.2.1 and Figure 5.2.2.4. Sample locations are identified by NAFO Divisions. Mean estimates provided with $95 \%$ credible interval in parentheses. Estimates of mixture contributions not supported by significant individual assignments ( $\mathrm{P}>0.8$ ) are represented as zero and therefore all columns may not add up to 100. Credible intervals with a lower bound of zero, or close to zero, may indicate little support for the mean assignment value. Results for ICES Statistical Area XIV are also shown.

Figure 5.1.1.1. Map of south Greenland showing communities to which Atlantic salmon have historically been landed and corresponding NAFO divisions and ICES Statistical Areas.

Figure 5.1.1.2. Nominal catches and commercial quotas ( $t$, round fresh weight) of salmon at Greenland for 19602022 (top panel) and 2013-2022 (bottom panel). Total reported landings from 2013-2022 are displayed by landings type. A factory only quota was set from 2012-2014 and a single quota for all components of the fishery was applied starting in 2015. From 2016-2020 the overall quota was adjusted annually to account for overharvest the previous year. All fishers are required to have a licence to fish for Atlantic salmon starting in 2018.

Figure 5.1.1.3. Number of licences issued by license type (top), number of fishers reporting by license type (middle) and percent of licensed fishers reporting by license type (bottom). Detailed statistics are available from 1998 to the present. Starting in 2018 all fishers were required to have a license.

Figure 5.1.3.1. Exploitation rate (\%) for NAC 1SW non-maturing and Southern NEAC non-maturing Atlantic salmon at West Greenland, 1971-2021 (top) and 2012-2021 (bottom). Exploitation rate estimates are only available to 2021, as 2022 exploitation rates are dependent on 2023 returns. Unreported catch is included.

Figure 5.2.2.1. Map showing total samples and subsamples for West Greenland Atlantic Salmon fishery 2020 SNP-based analyses to estimate continent and region of origin. Pie charts are scaled to sample size and blue and grey areas represent the proportions genotyped and not genotyped.

Figure 5.2.2.2. Map showing total samples and subsamples for West Greenland Atlantic Salmon fishery 2021 SNP-based analyses to estimate continent and region of origin. Pie charts are scaled to sample size and blue and grey areas represent the proportions genotyped and not genotyped.

Figure 5.2.2.3. Map showing total samples and subsamples for West Greenland Atlantic Salmon fishery 2022 SNP-based analyses to estimate continent and region of origin. Pie charts are scaled to sample size and blue and grey areas represent the proportions genotyped and not genotyped.

Figure 5.2.2.4. Map of sample locations for the SNP-based genetic baseline for European (top) and North American (bottom) reporting groups. The EUB (European Broodstock) reporting group does not have a geographic location and is therefore not represented on the top map. See Table 5.2.2.1 for location abbreviations.

Figure 5.2.2.5. Percent of the sampled catch by continent of origin for 1982 to the present. Sampling did not occur in 1993 and 1994.

Figure 5.2.2.7. Number of North American and European Atlantic salmon caught at West Greenland from 19822022 (top) and 2013-2022 (bottom). Estimates are based on continent of origin by NAFO division, weighted by catch (weight) in each division. Numbers are rounded to the nearest 100 fish. Unreported catch not included.

Figure 5.2.2.8. Bayesian estimates of mixture composition of samples from the West Greenland Atlantic salmon fishery for 2020 by region and overall using the SNP baseline. Baseline locations refer to genetic reporting groups identified in Table 5.2.2.1 and Figure 5.2.2.4. See Table 5.2.2.6 for detailed results. Estimates of mixture contributions not supported by significant individual assignments ( $\mathrm{P}>0.8$ ) are not included.

Region assignment

Figure 5.2.2.9. Bayesian estimates of mixture composition of samples from the West Greenland Atlantic salmon fishery for 2021 by region and overall using the SNP baseline. Baseline locations refer to genetic reporting groups identified in Table 5.2.2.1 and Figure 5.2.2.4. See Table 5.2.2.7 for detailed results. Estimates of mixture contributions not supported by significant individual assignments ( $P>0.8$ ) are not included.

Region assignment

Figure 5.2.2.10. Bayesian estimates of mixture composition of samples from the West Greenland Atlantic salmon fishery for 2022 by region and overall using the SNP baseline. Baseline locations refer to genetic reporting groups identified in Table 5.2.2.1 and Figure 5.2.2.4. See Table 5.22.8 for detailed results. Estimates of mixture contributions not supported by significant individual assignments ( $P>0.8$ ) are not included.

Figure 5.3.1. Summary 2SW (NAC regions) and MSW (Southern NEAC) 2022 median (from the Monte Carlo posterior distributions) spawner estimates in relation to Conservation Limits/Management Objectives (CL/MO). The colour shading represents the three ICES stock status designations: Full (at full reproductive capacity: the 5th percentile of the spawner estimate is above the CL), At Risk (at risk of suffering reduced reproductive capacity: median spawner estimate is above the CL , but the 5 th percentile is below) and Suffering (suffering reduced reproductive capacity: median spawner estimate is below the CL )

## 6 Generic ToRs

ToR 5 was to "Address relevant points in the Generic ToRs for Regional and Species Working Groups for each salmon stock complex".
The Working Group considered each of these requests in turn. Table 6.1 summarizes the responses, including reference to report sections where requests have been addressed.

Table 6.1. Summary of the WGNAS considerations of the Generic ToRs.

```
ToR WGNAS response
```

a) Consider and comment on Ecosystem and Fisheries Overviews with a focus on:
a.i) identifying and correcting mistakes and errors (both in the text, tables and figures), and WG has not examined the EOs or FOs
a.ii) proposing concrete evidence-based input that is considered essential for the advice WG has not exambut is currently underdeveloped or missing (with references and Data Profiling Tool entries, ined the EOs or FOs as appropriate).
b) Conduct an assessment on the stock(s) to be addressed in 2023 using the method (assessment, forecast or trends indicators) as described in the stock annex; - complete and document an audit of the calculations and results; and produce a brief report of the work carried out regarding the stock, providing summaries of the following where relevant:
b.i) Input data and examination of data quality; in the event of missing or inconsistent survey or catch information refer to the ACOM document for dealing with missing data and the linked template that formulates how deviations from the stock annex are to be reported.

N/A for Covid but WG has resolved missing RF data
b.ii) Where misreporting of catches is significant, provide qualitative and where possible quantitative information and describe the methods used to obtain the information;

See Section 3.3, An- mate the percentage of the total catch that has been taken in the NEAFC Regulatory Area in 2022.
b.iv) For category 3 and 4 stocks requiring new advice in 2023, implement the methods rec- $N / A$, cat 1 stocks ommended by WKLIFE X (e.g. SPiCT, rfb, chr, rb rules) to replace the former 2 over 3 advice rule ( 2 over 5 for elasmobranchs). MSY reference points or proxies for the category 3 and 4 stocks (guidelines)
b.v) Evaluate spawning stock biomass, total stock biomass, fishing mortality, catches (projected landings and discards) using the method described in the stock annex;
b.v.1) for category 1 and 2 stocks, in addition to the other relevant model diagnostics, the recommendations and decision tree formulated by WKFORBIAS (see Annex 2 of https://www.ices.dk/sites/pub/Publication\ Reports/Expert\ Group\ Report/Fisheries\ Resources\ Steering\ Group/2020/WKFORBIAS_2019.pdf) should be considered as guidance to determine whether an assessment remains sufficiently robust for providing advice.

See Sections 3.3, 4.3, 5.3
b.v.2) If the assessment is deemed no longer suitable as basis for advice, provide advice us- N/A, cat 1 stocks ing an appropriate Category 2-5 approach as described in ICES technical guidance for harvest control rules and stock assessments for stocks in categories 2 and 3 or ICES.

[^5]$N / A$, not requested by NASCO, checked with NEAC FWI, not required for NAC or WGC
b.vi) Catch scenarios for the year(s) beyond the terminal year of the data for the stocks for N/A until year of which ICES has been requested to provide advice on fishing opportunities;
b.vii) Historical and analytical performance of the assessment and catch options with a suc- No time to do this cinct description of associated quality issues. For the analytical performance of category 1 and 2 age-structured assessments, report the mean Mohn's rho (assessment retrospective bias analysis) values for time series of recruitment, spawning stock biomass, and fishing mortality rate. The WG report should include a plot of this retrospective analysis. The values should be calculated in accordance with the "Guidance for completing ToR viii) of the Generic ToRs for Regional and Species Working Groups - Retrospective bias in assessment" and reported using the ICES application for this purpose.
c) Produce a first draft of the advice on the stocks under considerations according to ACOM Completed guidelines.
d) Review progress on benchmark issues and processes of relevance to the Expert Group.

## Annex 3: List of participants

| Member | Country |
| :---: | :---: |
| Ida Ahlbeck Bergendahl | Sweden |
| Julien April | Canada |
| Jan Arge Jacobsen | Faroe Islands |
| Hlynur Bárðarson | Iceland |
| Geir Bolstad | Norway |
| Cindy Breau | Canada |
| Colin Bull | UK |
| Mathieu Buoro | France |
| Gérald Chaput | Canada |
| Anne Cooper | Denmark (ICES) |
| Guillaume Dauphin | Canada |
| Sophie Elliott | Chair-invited Member |
| Dennis Ensing | UK (Northern Ireland) |
| Jaakko Erkinaro | Finland |
| Peder Fiske | Norway |
| Marko Freese | Germany |
| Jonathan Gillson | UK (England and Wales) |
| Stephen Gregory | UK (England and Wales) |
| Derek Hogan | Canada |
| Niels Jepsen | Denmark |
| Séan Kelly | Ireland |
| Richard Kennedy | Northern Ireland |
| MacKenzie Kermoade | Denmark (ICES) |
| Clément Lebot | France |
| Hugo Maxwell | Ireland |
| David Meerburg | Canada |
| Michael Millane | Ireland |

| Member | Country |
| :--- | :--- |
| Rasmus Nygaard | Greenland |
| James Ounsley | UK (Scotland) |
| Rémi Patin | France |
| Etienne Rivot | France |
| Martha Robertson (Chair) | Norway |
| Kjell Rong Utne | USA |
| Timothy Sheehan | Sweden |
| Tom Staveley | UK (England and Wales) |
| Andrew Taylor | Norway |
| Alan Walker (Chair) | Ireland |
| Vidar Wennevik |  |

## Annex 4: Reported nominal catch of salmon in numbers and weight

Reported nominal catch of salmon in numbers and weight (tonnes round fresh weight) by sea-age class. Catches reported for 2022 may be provisional. Methods used for estimating age composition given in footnote.

1. MSW includes all sea ages >1, when this cannot be broken down.

Different methods are used to separate 1SW and MSW salmon in different countries:

- Scale reading: Faroe Islands, Finland (1996 onwards), France, Russia, USA and West Greenland.
- Size (split weight/length): Canada ( 2.7 kg for nets; 63 cm for rods), Finland up until 1995 ( 3 kg ),

Iceland (various splits used at different times and places), Norway ( 3 kg ), UK Scotland ( 3 kg in some places and 3.7 kg in others),
All countries except Scotland report no problems with using weight to catergorise catches into sea age classes; mis-classification may be very high in some years.
In Norway, catches shown as 3SW refer to salmon of 3SW or greater
2. Based on catches in Asturias (80-90\% of total catch) 1993-2018, and on catches for all Spain in 2019-2020 with 2SW, MSW and Not-Specified assigned to MSW.
3. Iceland catches of wild fish only, i.e. excluding ranched fish
4. France data for 2019 and 2020 show catch number only, as reported by the recreational fishery that doesn't report catch weight.
5. Russian data extracted from NASCO website at https://nasco.int/conservation/third-reporting-cycle-2/
6. For Norway and Canada, fish reported as Small are assigned to 1 SW whereas those reported as Large are assigned to MSW
7. For France, fish reported as Small are assigned to 1SW whereas those reported as Large are assigned to NS
8. N.B. Totals include NS values which are not shown.

## Annex 5: WGNAS Stock Annex for Atlantic salmon

The table below provides an overview of WGNAS Stock Annex. Stock Annexes for other stocks are available on the ICES website Library under the Publication Type "Stock Annexes". Use the search facility to find a particular Stock Annex, refining your search in the left-hand column to include the year, ecoregion, species, and acronym of the relevant ICES expert group.

| Stock ID | Stock name | Last updated | Link |
| :--- | :--- | :--- | :--- |
| Sal.27.neac | Salmon (Salmo salar) in Northeast <br> Atlantic | April 2021 | Salmo salar |

## Annex 6: Glossary of acronyms used in this report

Note that this list does not contain SI units or terms used in formulae or some of the tables and figures.

1SW (One-Sea-Winter). Maiden adult salmon that has spent one winter at sea.
2SW (Two-Sea-Winter). Maiden adult salmon that has spent two winters at sea.
ACOM (Advisory Committee) of ICES. The Committee works on the basis of scientific assessment prepared in the ICES expert groups. The advisory process includes peer review of the assessment before it can be used as the basis for advice. The Advisory Committee has one member from each member country under the direction of an independent chair appointed by the Council.

ASC - Annual Science Conference of ICES.
ASF - Atlantic Salmon Federation.
ASRJV - Atlantic Salmon Research Joint Venture of Canada.
BEAM - Bycatch Evaluation and Assessment Matrix, developed by WGBYC.
Bpa - Biomass for precautionary approach.
CL (Conservation Limit). Demarcation of undesirable stock levels or levels of fishing activity; the ultimate objective when managing stocks and regulating fisheries will be to ensure that there is a high probability that undesirable levels are avoided, i.e. that stock levels exceed the undesirable levels.

CoASal "Conserving our Atlantic salmon as a sustainable resource for people of the North; fisheries and conservation in the context of growing threats and a changing environment". A project under the EU's Kolarctic project.
CPUE (Catch per Unit of Effort). A derived quantity obtained from the independent values of catch and effort.
$C \& R$ (Catch and Release). Catch and release is a practice within recreational fishing intended as a technique of conservation. After capture, the fish are unhooked and returned to the water before experiencing serious exhaustion or injury. Using barbless hooks, it is often possible to release the fish without removing it from the water (a slack line is frequently sufficient).
COVID-19 - Coronavirus pandemic.
CWT (Coded Wire Tag). The CWT is a length of magnetized stainless steel wire 0.25 mm in diameter. The tag is marked with rows of numbers denoting specific batch or individual codes. Tags are cut from rolls of wire by an injector that hypodermically implants them into suitable tissue. The standard length of a tag is 1.1 mm .

DCF (Data Collection Framework). Framework under which EU Member States collect, manage and make available a wide range of fisheries data needed for scientific advice.
DC-MAP (Data Collection Multi-Annual Programme). European Union multiannual programme which includes the Data Collection Framework.

DFO (Department of Fisheries and Oceans). DFO and its Special Operating Agency, the Canadian Coast Guard, deliver programs and services that support sustainable use and development of Canada's waterways and aquatic resources.

DNA (Deoxyribonucleic Acid). DNA is a nucleic acid that contains the genetic instructions used in the development and functioning of all known living organisms (with the exception of RNARibonucleic Acid viruses). The main role of DNA molecules is the long-term storage of information. DNA is often compared to a set of blueprints, like a recipe or a code, since it contains the instructions needed to construct other components of cells, such as proteins and RNA molecules.
DSG (diadromous subgroup). Pan-regional subgroup within the Regional Coordination Groups to coordinate and identify data collection needs for diadromous species in relation to the EU data collection regulation Data Collection Framework/Data Collection-Multi-Annual Programme.

DST (Data Storage Tag). A miniature data logger with sensors including salinity, temperature, and depth that is attached to fish and other marine animals.
eDNA - Environmental DNA.
EG - Expert Group of ICES.
ESRF - Canada's Environmental Studies Research Fund.
EU - European Union.
FAO - Food and Agriculture Organization of the United Nations.
FSC (Food, Social and Ceremonial fishery). Indigenous fishery in Canada for food, social or ceremonial purposes.

FWI (Framework of Indicators). The FWI is a tool used to indicate if any significant change in the status of stocks used to inform the previously provided multiannual management advice has occurred.

GFLK - Greenland Fisheries Licence Control Authority.
GINR - Greenland Institute of Natural Resources.
GLM (Generalized Linear Model). A conventional linear regression model for a continuous response variable given continuous and/or categorical predictors.

GoSL or GoStL - Gulf of St. Lawrence, Canada.
ICES (International Council for the Exploration of the Sea). A global organization that develops science and advice to support the sustainable use of the oceans through the coordination of oceanic and coastal monitoring and research, and advising international commissions and governments on marine policy and management issues.

IMR - Institute of Marine Research, Norway.
Interreg - European Union research funding scheme.
ISA - Infectious Salmon Anaemia
ISSG Diad - The Intersessional Sub Group Diadromous Fish of the Regional Coordination Groups (RCG's).

IYS - The International Year of the Salmon.
KNAPK - Kalaallit Nunaanni Aalisartut Piniartullu Kattuffiat, the Organization of Fishermen and Hunters in Greenland.

LAB / Lab (Labrador). Labrador, Canada.

LCM - The North Atlantic wide Life Cycle Model or Bayesean Life Cycle Model.
MSA - Missing Salmon Alliance, UK.
MSW (Multi-Sea-Winter). A MSW salmon is an adult salmon which has spent two or more winters at sea. These include 'maiden' fish that have yet to spawn for the first time, and repeat spawners.

MSY - Maximum Sustainable Yield.
MSY.Bescapement - A target based on the amount of biomass left to spawn.
NAC (North American Commission). The North American Atlantic Commission of NASCO or the North American Commission area of NASCO.

NAFO (Northwest Atlantic Fisheries Organization). NAFO is an intergovernmental fisheries science and management organization that ensures the long-term conservation and sustainable use of the fishery resources in the Northwest Atlantic.

NASCO (North Atlantic Salmon Conservation Organization). An international organization, established by an inter-governmental convention in 1984. The objective of NASCO is to conserve, restore, enhance and rationally manage Atlantic salmon through international cooperation taking account of the best available scientific information.

NCC (NunatuKavut Community Council). NCC is one of four subsistence fisheries harvesting salmonids in Labrador.

NEAC (North Eastern Atlantic Commission). North-East Atlantic Commission of NASCO or the North-East Atlantic Commission area of NASCO.

NEAC-N or N-NEAC (North Eastern Atlantic Commission- northern area). The northern portion of the North-East Atlantic Commission area of NASCO. Also described as 'Northern or northern NEAC'.

NEAC-S or S-NEAC (North Eastern Atlantic Commission - southern area). The southern portion of the North-East Atlantic Commission area of NASCO. Also described as 'Southern or southern NEAC'.

NF (Newfoundland). Newfoundland, Canada.
NG (Nunatsiavut Government). NG is one of four subsistence fisheries harvesting salmonids in Labrador. NG members are fishing in the northern Labrador communities.

NOAA - The National Ocean and Atmospheric Administration of the USA.
NPAFC - The North Pacific Anadromous Fish Commission.
PICES - The North Pacific Marine Science Organization.
PFA (Pre-Fishery Abundance). The numbers of salmon estimated to be alive in the ocean from a particular stock at a specified time. In the previous version of the stock complex Bayesian PFA forecast model two productivity parameters are calculated, for the maturing (PFAm) and nonmaturing (PFAnm) components of the PFA. In the updated version only one productivity parameter is calculated, and used to calculate total PFA, which is then split into PFAm and PFAnm based upon the proportion of PFAm (p.PFAm).
PFANAC1SW (PFA NAC 1SW). The non-maturing component of 1SW salmon, destined to be 2SW returns (excluding 3SW and previous spawners) is represented by the PFA estimate for year i.

PIT (Passive Integrated Transponder). PIT tags use radio frequency identification technology. PIT tags lack an internal power source. They are energized on encountering an electromagnetic
field emitted from a transceiver. The tag's unique identity code is programmed into the microchip's non-volatile memory.

PSAT - pop-off satellite tag.
R - a computer programming language.
RCG (Regional Coordination Group). Group(s) that coordinate and identify data collection needs in relation to the EU data collection regulations.

RDB - A Regional Database.
RDBES - Regional Database and Estimation System.
RENOSAUM (Rénovation de la stratégie de gestion du saumon en Bretagne) - A French man-agement-orientated research project.

RSD - red skin disease.
SAMARCH - A major research project with full title "SAlmonid MAnagement Round the CHannel". https://www.samarch.org

SeaMonitor - A major research project.
SeaSalar - A major research project with full title "ATLANTIC SALMON AT SEA - factors affecting their growth and survival". https://www.seasalar.no

SER (Spawner Escapement Reserve). The CL increased to take account of natural mortality between the recruitment date (assumed to be 1st January after first entering the sea) and the date of return to homewaters.

SEUPB - Special EU Programmes Body.
SFA (Salmon Fishing Areas). Areas for which the Department of Fisheries and Oceans (DFO) Canada manages the salmon fisheries.

SGBYSAL - ICES Study Group on the Bycatch of Salmon in Pelagic Trawl Fisheries.
Slim (limit reference point).
SLU - Swedish University of Agricultural Sciences.
SMOLTRACK - A major NASCO-coordinated, EU-funded major research project.
SNP (Single Nucleotide Polymorphism). Type of genetic marker used in stock identification and population genetic studies.

Spa - ICES Precautionary target reference point.
St P \& M or SPM - St Pierre and Miquelon, Islands of France south of Newfoundland.
SoBI - Strait of Belle Isle, Canada.
SU - Stock units.
TAC - Total Allowable Catch.
ToR - Terms of reference.
UK (United Kingdom of Great Britain and Northern Ireland). Salmon stocks are grouped and managed according to three UK jurisdictions: Scotland, England and Wales; Northern Ireland.

USA (United States of America).
VNIRO (PINRO) - Russian Federal Research Institute of Fisheries and Oceanography.
WGBAST - ICES Working Group for Baltic Salmon and Trout.

WGBYC - ICES Working Group on Bycatch.
WGC (West Greenland Commission). The West Greenland Commission of NASCO or the West Greenland Commission area of NASCO.

WGDIAD (Working Group on the Science Requirements to Support Conservation, Restoration and Management of Diadromous Species) A Working Group of ICES.

WGNAS (Working Group on North Atlantic Salmon). ICES working group responsible for the annual assessment of the status of salmon stocks across the North Atlantic and formulating catch advice for NASCO.

WKBaltSalMP I and II (ICES Workshop on Evaluating Draft Baltic Salmon Management Plan).
WKSALMODEL - ICES Salmon Life Cycle Modelling Workshop
WKSALMON II - ICES/NASCO Workshop 2 for North Atlantic Salmon At-Sea Mortality YOY - Young of the year.

# Annex 7: Data deficiencies, monitoring needs and research requirements 

#### Abstract

The Working Group recommends that it should meet in 2024 (Chair, Alan Walker (UK)) to address questions posed by ICES, including those posed by NASCO. In the absence of a formal invitation elsewhere, the Working Group intends to convene in the headquarters of ICES in Copenhagen, Denmark. The meeting will be held from 11-20 March 2024.

The following relevant data deficiencies, monitoring needs, and research requirements were identified:

\section*{North Atlantic (Section 2)}

Overview of predation by cormorants: No Atlantic salmon studies met the criteria for inclusion in a global meta-analysis of the effect of predation from cormorants (multiple Phalacrocorax species) on fish in general (Ovegård et al. 2021), and therefore, the range-wide effect of cormorant predation on Atlantic salmon populations remains unclear. More studies are required, and these must be statistically robust, with clear treatment-control setups so that confident conclusions can be made.

The creation of a database listing individual PIT tag numbers or codes identifying the origin, source or programme of the tags should be implemented on a North Atlantic basin-wide scale. This is needed to facilitate identification of individual tagged fish, taken in marine fisheries or surveys, back to the source. A database has been designed by Missing Salmon Alliance UK (MSA) and IMR in Norway, and hosted and maintained by Missing Salmon Alliance (https://shiny.missingsalmonalliance.org/tag-database/). The database provides a central, searchable tag data repository against which unknown PIT detections can be searched. It also holds information on tag detections from pelagic marine fish species in the eastern Atlantic region with a network of over 20 PIT detector stations operated at fish processing plants in several countries. Tag users should be encouraged to include these tags or tagging programmes as this greatly facilitates identification of the origin of tags recovered in fisheries or tag scanning programmes in other jurisdictions.

## Northeast Atlantic Commission (Section 3)

Data call submissions were not received for the following NEAC jurisdictions with known/historic salmon fisheries or farmed salmon production: Ireland, Russia, Faroe Islands, Portugal, Germany. Equivalent data from Ireland and Faroe Islands were received via national reports to the Working Group. The Working Group understands there was no commercial catch in Germany in 2022, but that there may have been a small amount of recreational catch but the amount has not been reported. ICES recommends that all countries submit salmon data through the data call process as this is the most effective and efficient way for the Working Group to automate the data collation, quality assurance, analyses and reporting.

Data on catch numbers, exploitation rates and unreported catch rates were not available to the Working Group for the years 2021 and 2022 for any of the four Russian stock units. In the absence of data, exploitation rates and unreported catch rates together with their associated errors were assumed unchanged from previous years. With respect to catches, the total catch for Russia in wet mass for all stock units and sea ages combined was available for both 2021 ( 55.38 t ) and 2022 $(48.82 \mathrm{t})$ (NASCO, 2023). The ratios of the total catch for Russia in 2021 and 2022 to the mean total catch for the last five years of available stock unit data (2016 to 2020) were used to scale the mean catches by sea age and stock unit for the same five-year period to derive estimated catches for

2021 and 2022. The method developed to fill these data gaps might be improved with time, but if the true data cannot be used in future years then the levels of uncertainty in the derived data will increase and at some time point will reach a level that means the process should not be applied.

No river-specific CLs have been established for Denmark, Germany and Spain. Iceland has set provisional CLs for all salmon producing rivers and continues to work towards finalizing an assessment process for determining CL attainment.
The review of risk of bycatch conducted by the Working Group identified that although it was clear that at present salmon are caught as bycatch in coastal areas when they migrate to and from their natal rivers, but insufficient information exists on coastal fisheries to be able to evaluate coastal bycatch risk.

From this review of literature on salmon bycatch the Working Group has identified the following data deficiencies, monitoring needs and research requirements:

1. Improved understanding of post-smolt and adult salmon migration route in time.
2. Move to a quantitative analysis of the risk of exposure and bycatch risk to stocks which requires access to gear and fisheries specific fishing effort data (both inshore and offshore data) at an ICES rectangle by month.
3. Include salmon on ICES WGBYC list of species and data calls. WGBYC undertake data calls for the data required to analyse bycatch that WGNAS does not have access to. WGBYC also undertakes similar and overlapping analysis.
4. Standardize salmon bycatch monitoring programmes across countries, including minimum effort per fishery and standards for data recording and reporting.
5. Improve at-sea and onshore observer screening, including better salmon identification guidance. Minimum data to be collected are: date, fishery, catch location, number of salmon bycatch, fork length (preferably) and/or weight. The screening of discards from factories should also be explored (recommendation from ICES, 2004) by having close collaborations with factories operators.
6. Since at present bycatch data collection is difficult to access, eDNA data collection from scientific and commercial pelagic trawls may help improve detection of salmon and improve knowledge of their migratory pathways. Uncertainty estimates from these analyses are required.

## North American Commission (Section 4)

Complete and timely reporting of catch statistics from all fisheries for all areas of eastern Canada is recommended.

Improved catch statistics and sampling of the Labrador and SPM fisheries is recommended. Improved catch statistics and sampling of all aspects of the fishery across the fishing season will improve the information on biological characteristics and stock origin of salmon caught in these mixed-stock fisheries. A sampling rate of at least $10 \%$ of catches across the fishery season would be required to achieve a relatively unbiased estimate.

Additional monitoring in Labrador should be considered to estimate stock status for that region. Additionally, efforts should be undertaken to evaluate the utility of other available data sources (e.g. Indigenous and recreational catches and effort) to describe stock status in Labrador.

In all areas of eastern Canada, there is no estimate of salmon released as bycatch in recreational fisheries targeting other species.
The Working Group recommends for future meetings evaluating how 2 SW spawner requirement should be estimated and applied, especially for jurisdictions that have both Limit Reference Points and Upper Stock Reference points. Currently in NAC, some jurisdictions' 2SW spawner
requirements are based on a Limit Reference Point while others are based on an Upper Stock Reference point. These varying approaches raise consistency issues and should be addressed.

## West Greenland Commission (Section 5)

No recommendations specific to this section were made.

## Annex 8: ICES WGNAS Data call review

## Data submitted to ICES

Data were sent to ICES and the files were collated and provided in a directory on the Expert Group SharePoint site.

## Data Call template schema

The Data Call provided a template schema (Excel spreadsheet DC_Annex_7.12.1 WGNAS Template) with a glossary and vocabulary codes plus predefined columns and descriptions of data fields and codes (drop-down menus) for several of the data fields.
Several revisions were made to the 2023 template prior to publication. These are described below, along with some further revisions to be implemented in the 2024 template.

## Geographic area descriptors

The Atlantic Salmon Data Call schema currently has a hierarchical structure to define the stock units according to:

1. Commission: defined as the NASCO Commissions (NAC, NEAC, WGC)
1.1 Major Stock Unit: defined as countries or jurisdictions
1.1.1 Minor Stock Unit: not prescribed
1.1.1.1 River_Name: not prescribed

NASCO requires parties to report catches at the scale of Commission and Major Stock Unit as defined in the schema.

NASCO also requests estimates of worldwide aquaculture production of Atlantic salmon. A Major Stock Unit category (exNA) to describe activities outside the North Atlantic is provided.
The catch data are also used in the run reconstruction, stock status, and the development of catch advice by the Working Group. Future consideration could be made to compiling the catch data using a "Minor Stock Unit" category that corresponds to the stock units used in the North Atlantic wide Life Cycle Model; six stock units in NAC, seven stock units for southern NEAC, and eleven stock units for northern NEAC.

There was no Major Stock Unit code for the Netherlands in the 2023 template, so NL will be added to the drop-down options for 2024.

The NS option for Major Stock Unit will be removed from next year's template.

## Time period (YEAR)

The data were requested for the previous two calendar years (1 January to 31 December 2021, and 2022). This was because WGNAS had not collated the catch statistics in 2022.

## Codes for countries and jurisdictions (COUNTRY)

ICES is moving towards adopting the ISO_3166 list of country codes (https://vocab.ices. $\mathrm{dk} /$ ?ref=337). This list has separate codes for the four nations of the United Kingdom, but also a code for the England and Wales jurisdiction, which means that WGNAS can adopt these and move to that ISO-compliant scheme. These codes will also be adopted for Major Stock Units.

The codes changes will apply to the United Kingdom jurisdictions (GB-SCT, GB-EAW, GB-NIR), and St Pierre and Michelon (PM).

Exceptions to this apply to Iceland and Sweden that have Wild and Ranched stock units, and Greenland that has East and West stock units which have been retained with WGNAS codes because there are no ISO_3166 codes for these.

## A new Gear Type column (G_TYPE)

This new data descriptor was created to specify catches by rod, for table 2.1.2.1 and figure 2.1.2.1 which present data for Rod Fisheries. Previously, it had been assumed that all Recreational and Ranched catches were by rod. As well as ROD, drop down options were created for OTHER to capture all gears other than rods, and NS for farmed production since production weight is reported but these salmon are not fished (except escapees but these are included in some national rod and/or net catch data).

Table 3.1.3.1 in the NEAC section presents data for a larger range of fishing gears. If a future datacall is used to generate tables and figures for commission areas, then the drop down options for GEAR will be expanded.

## Sea age/Size class (SEA_AGE_SIZE_CLASS)

The PS (Repeat spawner) code was missing from the Sea-Age section in the Vocabulary sheet. This has been added to the drop down lists.

Norway reported catches as Small or Large salmon, having converted from their national reporting scheme of Small, Medium and Large salmon. The latter is equivalent to 1, 2 and 3 SW age classes. Reporting against these age classes would not affect data presentation in Section 2, and would simplify the data generation for Annex 4 (catches by sea age), and therefore Norway will report against sea age from 2024 onwards.

## Fishing Area (F_AREA)

Some countries had recorded their Farmed salmon production as being COASTAL. While spatially correct, this causes an error in the calculation of catches by fishing area. Therefore, the option to report Fishing Area as Not Pertinent (NP) has been added.

## Missing data descriptors

Entries were not provided for all data descriptors in this year's submissions. Blank data descriptors risk that those data are not recognized by the script that generates the tables and figures. Therefore, all data descriptors must be completed, and this will be emphasized in the 2024 Datacall guidance.

Not all catch data, in number or weight, can be reported. An explanation for missing data for catch weight or catch number (empty cells) should be provided using codes in the variable called "DATA_QUALITY", as defined below.

| DATA_QUALITY |
| :--- | :--- |
| NR $\quad$Not reported: data or activity exist but numbers are not reported to authorities (for example for commercial <br> confidentiality reasons). |
| ND $\quad$No data: where there are insufficient data to estimate a derived parameter. <br> NC <br> Not collected: activity / habitat exists but data are not collected by authorities (for example where a fishery ex-$\quad$Not Pertinent: where the question asked does not apply to the individual case (for example where catch data <br> are absent as there is no fishery or where a habitat type does not exist). |

At present, fisheries that are closed can be identified using the DATA_QUALITY field (code = NP). To be complete, each submission would minimally contain one row for each F_TYPE (REC, COM, RAN, FARM, INDG, SUBS). If any of these activities do not occur because they are not authorized, the catch data fields would be blank, the DATA_QUALITY field would be coded NP, and data fields for F_AREA, SEA_AGE/size class, FATE, and Reporting_class would all be coded NS (non-specific).

Reporting was not as complete as this specification, i.e. some countries only reported rows where fisheries existed. This was not an issue while the data were extracted manually, and has not been an issue for the automated extraction this year, but will need annual review.

## Quality control / quality assurance

All countries/jurisdictions in the North Atlantic with present or historic catches of Atlantic salmon or farmed salmon productionare expected to respond to the Data Call request from ICES. The date for response, one week ahead of the start of WGNAS meeting, should be sufficient to allow checking of the entries in the days before or at the start of the meeting, prior to running the collation, analyses and reporting. An earlier request date could not be accommodated by all jurisdictions. For most jurisdictions, the data for the most recent year provided are provisional.

ICES will maintain the Data Call submissions for each year on the Working Group SharePoint site.

If countries need to resubmit data from previous years, ICES will provide the most current data sheet to a requesting party to which revisions could be made and returned to ICES.

# Annex 9: Working Paper 1 - Data deficiencies Russian Federation data 

Authors: James Ounsley, Etienne Rivot, Geir Bolstad, Hugo Maxwell, Jonathan Gillson, Alan Walker

## Introduction

In the absence of data from the Russian Federation being reported to ICES for 2021 or 2022, the Working Group investigated alternative published sources of data and developed an approach to make those data usable for the assessment model.

The national total catch weights for fisheries in coastal waters, estuaries and in-river, the numbers of salmon caught and released, and this number expressed as a percentage of the total catch retained and released, are annually reported to NASCO in the Russian Federation's Annual Progress Report (APR). These reports are published on the NASCO website (at https://nasco.int/con-servation/third-reporting-cycle-2/) and therefore the Working Group used these data to collate catch summaries for the North Atlantic, as reported in section 2 of the Working Group report, and the draft 'sal.other.all' advice.

In addition, however, the Working Group requires catch numbers by stock unit (4 stock units considered in Russia) and sea age class, to conduct the pre-fishery abundance and run reconstruction analyses. Data disaggregated to these levels are not reported to NASCO and therefore the Working Group developed an approach to derive estimated values for 2021 and 2022. The following text describes that approach, considers the strengths and weaknesses of this approach, makes suggestions for alternative approaches that might be examined in the future, and outlines issues with all of these.

## Absence of Russian data

There are four regional stock units (SU) within Russia: Pechora River (RP), Archangel / Karelia (AK), Kola / White Sea (KW) and Kola / Barents Sea (KB). This split in the Russian stock is based on biological characteristics and the resolution of catch statistics reporting.

For each of the four SU, the NEAC Run Reconstruction model requires the following annual input data: catches by sea age (and additionally catches on delayed spawners for KW); declared returns for RP by sea age; exploitation rates and associated error by SU and sea age and unreported catch rates and associated error by SU and sea age.

WGNAS agreed upon an approach for accounting for the deficiency by constructing estimated values for the affected years (2021 and 2022) based on a set of assumptions given historic data.

## Exploitation rates and unreported catch rates

For all four regional stock units, the exploitation rates and unreported catch rates, together with their associated errors, have been unchanged for at least the last ten years for which they have been provided to WGNAS. These values were assumed unchanged for the 2021 and 2022 stock years.

## Estimating the catch

For the three stock units AK, KB and KW, the estimated catches for 2021 and 2022 were based on the five years mean of the most recent reported catches (i.e. catches for the period 2016 to
2020). Total catches for the entire Russian stock are available for 2021 and 2022 (NASCO, 2023), and provide information on the aggregate trend in catches at the country level. This information is incorporated into the estimated catches by scaling the five years mean for each stock unit by the relative change in catches observed in the total catch between 2021 and 2022 and the five-year mean of total catch for the period 2016 to 2020.

Given total catch for Russia $T_{y}$ in years $y=2021,2022$, we derive the scaling factor $\alpha_{y}$ for year $y$ as follows.

$$
\alpha_{y}=\frac{T_{y}}{\frac{1}{5} \sum_{i=2016}^{2020} T_{i}} .
$$

The catches $C_{s, a, y}$ for each stock unit $(s)$ and sea age $(a)$ are then estimated by:

$$
C_{s, a, y}=\alpha_{y} \frac{1}{5} \sum_{i=2016}^{2020} C_{s, a, i}
$$

For RP, the declared returns $R_{a, y}^{\mathrm{dec}}$ were estimated using the same method

$$
R_{a, y}^{\mathrm{dec}}=\alpha_{y} \frac{1}{5} \sum_{i=2016}^{2020} R_{a, i}^{\mathrm{dec}}
$$

The resultant estimates can be seen in Figure 1.
The catches on delayed spawners in KW for 2021 and 2022 were estimated using the same approach. These values are used in the derivation of spawners for this region, but are not influential on the variance in any of the derived values of the NEAC run-reconstruction and are not considered in the following analysis.

Figure 1. Reported (2016-2020) and estimated (2021, 2022) catches for the regional stock units $A K, K B$ and $K B$ and declared returns for $R P$

## Accounting for additional uncertainty

The NEAC run-reconstruction model uses the catches (and declared returns for RP) to derive returns to home-waters and thereafter spawning abundances and PFA. Uncertainty in these
values is introduced by integrating over uncertainty in the exploitation rates and unreported catch rates when deriving returns to home-waters. Uncertainty is integrated out using Monte Carlo numerical simulations.

For $\mathrm{AK}, \mathrm{KB} \& \mathrm{KW}$, the returns $\left(R_{s, a, y}\right)$ are derived as follows:

$$
\begin{aligned}
R_{s, a, y} & =\frac{C_{s, a, y}}{E_{s, a, y}\left(1-U_{s, a, y}\right)} \\
E_{s, a, y} & \sim \operatorname{unif}\left(\mu_{s, a, y}^{E}-\epsilon_{s, a, y}^{E}, e+\epsilon_{s, a, y}^{E}\right) \\
U_{s, a, y} & \sim \operatorname{unif}\left(\mu_{s, a, y}^{U}-\epsilon_{s, a, y}^{U}, e+\epsilon_{s, a, y}^{U}\right) .
\end{aligned}
$$

Where $E_{s, a, y}$ and $U_{s, a, y}$ are the distributions of the exploitation rates and unreported catch rates as defined by uniform distributions defined by their respective means ( $\mu_{s, a, y}^{E}, \mu_{s, a, y}^{U}$ ) and half range $\left(\epsilon_{s, a, y}^{E}, \epsilon_{s, a, y}^{U}\right)$.

For RP, the returns are defined as

$$
\begin{aligned}
R_{s, a, y} & =R_{a, y}^{\operatorname{dec}}(1+U) \\
U_{s, a, y} & \sim \operatorname{unif}\left(\mu_{s, a, y}^{U}-\epsilon_{s, a, y}^{U}, e+\epsilon_{s, a, y}^{U}\right)
\end{aligned}
$$

To account for the fact that the catches (or declared returns for RP) were not available as data in 2021 and 2022 but first derived from the total catch in weight based on the method describe above, an approach was developed to scale up the variance of the probability distribution of the returns (and by extension spawner abundances and PFA) for 2021 and 2022. This was to ensure that the confidence intervals around the returns estimates for these years were more likely to include the mean value of the returns based on the true data had it been available (Figure 2, a and b).

Let $R_{l, y}^{e s t}$ be the estimated returns for year $y$ with lag $l$. The lag defines the number of years since the year of the most recent reported data used in the derivation of the estimated catches (or declared returns for RP). For example, for 2021 with a lag of $l=1$, the returns are relative to the five years average of data for 2016 to 2020, and for 2022 with a lag of $l=2$, the returns are relative to the five years average for the same period. For clarity, the following derivation is for a single stock unit and age class. The derivation is the same of all four stock units and sea ages.

Let $R_{l, y}^{a d j}$ be the adjusted returns after scaling up the variance of the estimated returns. The variance of the log returns can be scaled by multiplying the centered log returns by some scaling factor $q$ as follows:

$$
\ln \left(R_{l, y}^{a d j}\right)=q_{l}\left(\ln \left(R_{l, y}^{e s t}\right)-E\left[\ln \left(R_{l, y}^{e s t}\right)\right]\right)+E\left[\ln \left(R_{l, y}^{e s t}\right)\right]
$$

such that

$$
\operatorname{var}\left[\ln R_{l, y}^{a d j}\right]=\operatorname{var}\left[q_{l} \ln R_{l, y}^{e s t}\right]=q_{l}{ }^{2} \operatorname{var}\left[\ln R_{l, y}^{e s t}\right]
$$

To capture the additional uncertainty resulting from the use of estimated data, it remains to find the scaling factor $q$ such that

$$
\operatorname{var}\left[\ln R_{l, y}^{a d j}\right]=r_{l}+\gamma_{l}
$$

where $\gamma_{l}$ is the expected variance of the estimated log-returns and $r_{l}$ is the expected mean squared error between the estimated log-returns and the observed $\log$ returns, i.e. the returns derived from observed catches (or declared returns for RP), denoted $R_{y}^{o b s}$.

The required adjustment of the variance is then given by:

$$
q_{l}=\sqrt{\frac{r_{l}+\gamma_{l}}{\gamma_{l}}}
$$

In the absence of $R_{y}^{\text {obs }}$ for the years 2021 and 2022, a one step ahead "cross-validation" approach was developed to numerically quantify the expected $r_{l}$ and $\gamma_{l}$, denoted $\widehat{r}_{l}$ and $\widehat{\gamma}_{l}$, based on $R_{y}^{o b s}$ for the $y$ in 2016 to 2020 and $R_{l, y}^{e s t}$ derived for the same $y$ and for $l=1$ and $l=2$. Giving the numerically estimated $\widehat{q_{l}}$

$$
\widehat{q}_{l}=\sqrt{\frac{\widehat{r}_{l}+\widehat{\gamma}_{l}}{\widehat{\gamma}_{l}}} .
$$

Thus, $\widehat{r}_{l}$ was calculated as the mean of the squared difference between the means of the estimated and observed returns on the log scale, calculated over a 5 years window:

$$
\widehat{r}_{l}=\frac{1}{5} \sum_{y=2016}^{2020}\left(E\left[\ln \left(R_{l, y}^{e s t}\right)\right]-E\left[\ln \left(R_{y}^{o b s}\right)\right]\right)^{2}
$$

Similarly, $\widehat{y}_{l}$, was calculated as the mean of the variance of the estimated returns on the log scale, calculated over a 5 year window:

$$
\widehat{\gamma}_{l}=\frac{1}{5} \sum_{y=2016}^{2020} \operatorname{Var}\left(\ln \left(R_{l, y}^{e s t}\right)\right)
$$

A comparison of $R_{y}^{o b s}, R_{l, y}^{e s t}$ and $R_{y}^{o b s}$ for the time period 2016 to 2020 are shown in Figure 2 a, with $l=1$ and Figure 2 b . with $l=2$.

Results. Adjusted returns compared to observed returns (years 2016-2020)
For the 1SW components of $\mathrm{AK}, \mathrm{KB}$ and KW the observed returns are not well captured by the estimated returns. This discrepancy is mostly driven by large variability in observed 1SW returns for those stock units, which is not captured by the five year averages underpinning the estimated returns. The result of this is a large increase in the variance of the adjusted returns relative to the estimated returns, which successfully captures the observed returns. A similar dynamic is present in the MSW component of the KW stock unit.

For the RP stock unit, the variation in the observed returns is small. This is due to the declared returns being directly observed, and uncertainty in the returns being introduced by integration over the uncertainty in the unreported catch rate only. This results in a substantial increase in the variance when deriving the adjusted returns. Again, the adjusted returns successfully capture the observed returns.

Figure 2 a. Distribution of 'observed' returns based on reported values for catches (declared returns for $R P)$, returns based on estimated values and returns based on estimated values with adjusted variance for the four regional stock units of Russia and 1SW and MSW stocks. Estimated catches and declared returns are based on five years average lagged by 1 year. Points show the mean value, error bars show the $5^{\text {th }}$ and $9^{\text {th }}$ quantiles, $y$-axis on the $\log$ scale.

Figure $2 b$. Distribution of 'observed' returns based on reported values for catches (declared returns for $R P)$, returns based on estimated values and returns based on estimated values with adjusted variance for the four regional stock units of Russia and 1SW and MSW stocks. Estimated catches and declared returns are based on five years average lagged by 2 years. Points show the mean value, error bars show the 5 th and 9 th quantiles, $y$-axis on the log scale.

Results. Adjusted prediction of returns, years 2021 and 2022
Figures 3 shows the returns for 2021 and 2022 based on estimated catches (or declared returns for RP) before and after adjusting the variance to account for the additional uncertainty, together with the historic estimates of returns based on reported catch (or declared returns for RP).

As expected from the prior analysis, the increase in the variance is most pronounced for the RP region and where historic returns estimates have high variability. While the uncertainty adjustments are large, this is reflective of genuine additional uncertainty in the returns in the absence of data and represents a conservative approach.

Figure 3. Returns based on reported values (2016 to 2020) and estimated returns with and without adjusted variance $(2021,2022)$ for the four regional stock units in Russia and the 1 SW and MSW stocks. Error bars show the 5th and 95th quantiles

## Discussion

The proposed method constitutes one approach for providing the input data needed for the run-reconstruction and PFA models based on the total catches in weights reported by Russia to NASCO. It was developed by the Working Group in 2023 for the purposes of assessing the Russian stocks in 2021 and 2022. However, the approach is based on strong hypotheses and has limitations. If this situation continues, a robust approach to handling this deficiency going forward is desired. The Working Group anticipates exploration of the following issues; some of which could be addressed during the WGNAS benchmark process (BWKSalmon).

- The method used to scale the variance relies on the last five years of available data, and all years in this five-year window have the same weight in the analysis. The choice of a five-year window was made based on the assumption that more recent data would be more representative of the present. Alternative methods could consider data from additional years in the time-series, weighting the influence of each year by recency. Using time-series-based statistical models to capture the influence of previous years while avoiding the strong hypothesis of a simple average could also be investigated.
- Implicit in this approach is the assumption that each stock unit covaries with the total catch in tonnage. Indeed, the approach scales the expected catches in each of the four regions using the same scaling factor (the ratio of the total catches in weight between the last years of data and the predicted years). To address this limitation, alternatives approaches could be developed to stochastically model the split between the four regions (and the same holds for the split between sea-ages within regions). Modelling the split using Multinomial or Multinomial-Dirichlet distributions would allow for stochasticity in the split while ensuring that estimated catches for each stock unit and age class sum to the total reported tonnage of fish at the scale of Russia.
- Any method used to disaggregate the catch in Russia that is based on historic data will become less applicable the more time passes since the data were last updated. Hence, to
enhance robustness, an alternative method would be to modify the assessment model by aggregating the four stock units of Russia to a single stock unit. The implications of this approach, given a biological basis for the current split, should be considered.

# Annex 10: Working Paper 2 - Risks of salmon bycatch occurring in pelagic and coastal fisheries, and the effectiveness and adequacy of current bycatch monitoring programmes 

AUTHORS: Sophie Elliott, Kjell Rong Utne, Hlynur Bardarson, Cindy Breau, Alan Walker

## Background

This chapter addresses terms of reference which was set to answer the following request put forward by NASCO 2022 (ToR) 2.4: "advise on the risks of salmon bycatch occurring in pelagic and coastal fisheries, and report on effectiveness and adequacy of current bycatch monitoring programmes". The spatial scope of the ToR was the North East Atlantic Commission (NEAC) area.

Anadromous Atlantic salmon undertake lengthy oceanic migrations through the North Atlantic, growing for 1-4 years at sea before returning to their natal rivers to spawn. Although descriptions of their migratory behaviour and their distribution in time and space are not precisely known, observations indicate that they occupy the pelagic zones of the water column as they move out of coastal waters and throughout their oceanic migration (Gilbey et al., 2021; Rikardsen et al., 2021; Utne et al., 2022). Once an important commercial species, salmon have suffered serious population declines throughout their distribution (ICES 2022a). Much research has been dedicated to improving stocks during their freshwater life-history phases, yet little improvement has been observed for salmon abundance (ICES 2022a). Reduced marine survival has been implicated as a key reason for their decline (Olmos et al., 2020; Thorstad et al., 2021).

During some periods of their at-sea feeding migration and on their return migration the postsmolt, pre-adult and adult salmon are likely to pass through areas with intensive commercial fishing (ICES 2005). The potential risk of interception by fisheries has long been recognized. ICES examined risk from pelagic oceanic fisheries in the early-2000s, prompted by observations of large number of post-smolt Atlantic salmon taken together with large catches of mackerel in Norwegian research surveys in the Norwegian Sea fisheries in the late 1990s. In addition, in 2003 WGNAS received indications that the herring fisheries occurring in August in northerly areas of ICES areas might intercept adult salmon. ICES Study Group on the Bycatch of Salmon in Pelagic Trawl Fisheries (ICES 2004, 2005) reviewed and analysed the spatial and temporal distribution of migrating salmon against the major pelagic fisheries in the Norwegian Sea, the North Sea, and areas west and south of UK and Ireland.

SGBYSAL 2004 made a series of recommendations, from screening research and commercial catches and discards for salmon to the development of methods for estimating salmon post-smolt bycatches (ICES 2004). The application of a range of bycatch estimates to known data on salmon abundance and survival trends in the stocks in question is recommended to determine whether crude levels of potential bycatch can account for recent changes in abundance or survival at sea. Nonetheless little has been done since these recommendations and some of the pelagic fisheries have changed their spatial and temporal distributions and fishing capacity since then prompting the call for a re-examination of the risk.

While the spatial scope of ICES $(2004,2005)$ focused on Northern oceanic waters, the coastal corridors between natal rivers and oceanic feeding waters have a range of fisheries with gears
that have the potential to intercept salmon, both on their outward and return journeys. More recently, WKSALMON2 has proposed further investigations of the spatial and temporal distributions of fisheries using pelagic gears that might intercept salmon at sea, and ICES has published a data call (ICES 2023a - WKSalmon). The data from that call will not be available within the timing of the WGNAS 2023 meeting, and therefore we would anticipate further analyses and investigations later in 2023. A better understanding of coastal pressures is yet to be examined as requested by NASCO.

ICES (2005) noted that one major drawback for evaluating the potential of salmon being intercepted by pelagic fisheries is that their distribution throughout the year and migration routes in certain areas still are relatively poorly known. Here we review advancements in this area and the overlap between recorded landings from pelagic and coastal fisheries and recorded salmon distribution. A separate draft advice document has been prepared by WGNAS, for consideration of the Advice Drafting Group for Salmon (ADGSalmon).

## Advise on the risk of bycatch

Salmon are mainly bycaught in pelagic trawls and static net fisheries such as gillnets (Elliott et al., 2023a; Gilbey et al., 2021; ICES 2005). They are, however, also caught by bottom trawls, bottom longlines, and purse-seine fisheries (Elliott et al.,2023a; ICES 2005; ICES 2020). Although it is known that salmon can be bycaught by a range of gear, the risk of salmon bycatch is unknown.

ICES Working Group on Bycatch (WGBYC) has a detailed plan to monitor the bycatch of Protected Endangered and Threatened Species (PETS; ICES 2022b). Through this working group, official data calls have been undertaken yearly since 2018 to report incidental bycatch data at a regional scale through the EU Data Collection Framework (DCF). Although nations can refuse to provide data, WGBYC also ensures linkups with other working groups which require information on the bycatch of PETS species. Despite salmon being listed as 'Vulnerable' on the IUCN EU red-list and protected through various national and international conventions and Directives (Habitat Directive, Bern and convention, OSPAR, etc.), it is not listed on WGBYC at present, since WGNAS is responsible for salmon assessment. Discussions with ICES secretariates are in place to add salmon to their list in 2025 at the earliest.

## Bycatch definition

Since salmon is a protected and threatened species, we have adopted a modified version ICES WGBYC definition for bycatch: According to ICES Roadmap for bycatch advice on PETS incidental bycatch is defined as all catches of species (including species not landed or released) "not targeted in fisheries operations (incidentally/accidentally caught), including those not taken on board, regardless of later treatment." (ICES 2022c). This modified version of WGBYC definition was adopted with the addition of non-catch losses.

If we were to qualify this definition according to whether the bycatch influences stock status, we might define the "material bycatch" as the mortality (directly or indirectly) of salmon arising from contact with fishing gears targeting other species with the potential of impacting the reproductive capacity of a salmon stock.

To keep in mind, the Food and Agricultural Organization (FAO) definition for bycatch and related definitions are:

- Bycatch: "Component of the catch which represents non-targeted fish associated with the catch of the target species or group towards which fishing effort is directed, or other aquatic organisms taken incidentally during the course of fishing (e.g. birds, mammals, reptiles, invertebrates). Some or all of the bycatch may be returned to the sea as discarded catch, either dead or alive. The catch taken incidentally is also referred to as incidental
catch" (https://www.fao.org/cwp-on-fishery-statistics/handbook/capture-fisheries-sta-tistics/catch-and-landings/en/).
- Discarded catch: "Estimated component of the catch which is the total live weight of undersized, unsaleable, or otherwise undesirable whole fish and other aquatic organisms which are discarded at the time of the capture or shortly afterwards. Discarded catch refers to whole fish and other aquatic organisms discarded dead or alive, and may include species taken as bycatch. Discarding in some fisheries is prohibited".
- The total catch "is that quantity taken by the fishing gear and which reaches the deck of the fishing vessel. DISCARDS is that portion thrown away at sea (for one reason or another). The remainder is the landed catch or retained catch (i.e. that which is brought ashore) which can be further subdivided into target catch and incidental catch, bearing in mind the volume, value, the incidence of species caught and the nature of the fishing operations"(https://www.fao.org/3/w6602e/w6602E03.htm).

## Collecting data on salmon bycatch

"Although bycatch of salmon is difficult to access (particularly at a fine resolution), it can provide key information on mortality, their spatial distribution and migratory pathways (Elliott et al., 2023a; Gilbey et al., 2021; ICES 2005). With enough and sufficiently detailed bycatch data, estimations of bycatch can also be undertaken (ICES 2004; ICES 2005; ICES 2020; ICES 2022a). Methods of recording and calculating discards can also vary between fisheries (e.g. Ulleweit et al., 2010; Couperus et al., 2004). These biases may therefore lead to underreporting (ICES 2022c; ICES 2013; Olafsson et al., 2016)" (text from ICES 2023a).
"As part of the EU data collection framework, bycatch monitoring is mandatory. Most fish species have low bycatch survival rates, and for some gears are not easily observed, and therefore are not recorded. Various methods exist to log bycatch, including fisheries observer records, logbook data (also referred to as landings data) and fish market data collection methods (Table 3.5; ICES 2022a). Bycatch data are, however, not openly accessible, and an ICES data call is required to access such data" (text from ICES 2023a).

## Risk of bycatch

There are two types of risk which need to be considered to understand salmon bycatch risk:

## The Risk of Exposure

Here we define risk of exposure as the "risk depends on the salmon being in the same place as a vessel fishing a type of gear that would intercept (catch or kill) salmon and at a depth where the salmon would be. In an ideal world, we would know the instantaneous positions of the salmon and these fishing gears." The risk of exposure to fisheries is therefore spatially and temporally dependent. Through WKSALMON, a data call has been requested to improve understanding of the potential overlap in space and time between salmon migration and pelagic fisheries (ICES 2023a). Through this data request, monthly pelagic (Mackerel, Herring, Blue whiting, Horse mackerel, Capelin, Chub mackerel, and Sardine) fishing activity data (derived from aggregated Vessel Monitoring System (VMS) and landings information) has been requested from WGWIDE at an ICES rectangle scale from 2000 to 2022 to be able to try to overlap the migration of salmon with the pelagic fishing effort.

Through work undertaken by WGBYC (ICES 2022c), an understanding of the spatial fishing effort (Days at Sea) by different gear categories is possible to gauge from the ICES division scale map (Figure 1, fishing effort for 2019 and 2021). However, for this to be of use to understanding salmon bycatch, this fishing effort information is required on a finer spatial (ICES rectangle $1 \times 0.5$ decimal degrees) and temporal (monthly) scale to match to salmon migrations.
If accessing such temporal (monthly) fishing effort data at the spatial scale (ICES rectangle) required to understand the bycatch risk of salmon is complicated to access, the risk of exposure
can be gauged through freely accessible Global Fishing Watch (GF W) data from 2012 to 2022 (https://globalfishingwatch.org/). Fine-scale fishing activity data are particularly important for coastal and inshore ( $<6 \mathrm{~nm}$ from the coast) fisheries to be able to link the activities to salmon rivers. GFW fishing effort data are derived from Automatic Identification System (AIS) data which is required for all vessels ( $>6 \mathrm{~m}$ long) to avoid a collision (see Appendix 2). Apparent fishing activity at $100^{\text {th }}$ of a degree resolution is calculated from fishing movement activity (Kroodsma et al., 2018a) in a similar way to VMS data. Due to difficulties in identifying precise gear types, fishing categories of similar movement types are grouped together for each data point (e.g. set gillnets, drifting longlines, trawlers, fixed gears, purse-seines, seiners, etc.). Although AIS can be turned off, and coverage for smaller vessels ( $<12 \mathrm{~m}$ long) is lower, a comparison of these data with ICES BYC fishing effort data, could provide insightful information into potential Illegal Unreported and Unregulated Fisheries (Kroodsma et al., 2018; Welch et al., 2022; Appendix 2).

Fishing effort
(days at sea)

Figure 1. Métier level 3 fishing effort (days at sea) submitted to the WGBYC database (Figure from ICES 2022c)

## The Risk to the Stocks

According to the latest report of the WG on catch advice for the Faroes fishery which was developed for the 2021/2022 to 2023/2024 fishing seasons, the status of the stocks do not allow any catch - and therefore the risk of any bycatch is high (ICES 2021a). In the Northern NEAC stock complex, over the forecast period, the non-maturing 1SW component has a high probability ( $\geq 95 \%$ ) of achieving its Spawner Escapement Reserves (SER) for Total Allowable Catch (TACs) at Faroes solely for a catch option of $\leq 20 t$ in the 2021/2022 season. The maturing 1SW component
in the Northern NEAC stock complex and both Southern NEAC stock complex components each have less than $95 \%$ probability of achieving their SERs with any TAC option in any of the forecast seasons. Therefore, there are no catch options that ensure a greater than $95 \%$ probability of each stock complex achieving its SER.

The probabilities of the non-maturing 1SW national management units achieving their SERs in 2021/2022 vary between $20 \%$ (UK, Northern Ireland) and $99 \%$ (Norway) with zero catch allocated for the Faroes fishery and decline with increasing TAC options. The only countries to have a greater than $95 \%$ probability of achieving their SERs with catch options for Faroes are Norway (TACs $\leq 40 \mathrm{t}$ ) and UK (England \& Wales) (TACs $\leq 40 \mathrm{t}$ ). In most countries, these probabilities are lower in the subsequent two seasons. There are, therefore, no TAC options at which all management units would have a greater than $95 \%$ probability of achieving their SERs. All bycatch must in same principal be considered as proposing a high-risk to the salmon stocks - especially in mixed-stock fisheries where stocks from both Northern- and Southern NEAC are present.

In coastal fisheries, the mixture of stock components is not the issue, but the status of stocks for individual countries, and even to the river-specific level becomes more relevant. An assessment of Pre-Fisheries Abundance (PFA) of salmon against Spawner Escapement Requirements (SER) and returns and spawners against Conservation Limits (CL) are estimated by the Working Group and shown for individual countries and by regional blocks in WGNAS reports (see e.g. ICES 2022d). In some coastal areas the surrounding stocks might be estimated at being "at-risk" or "suffering" full reproductive capacity, while in others the stocks might be estimated to be at full reproductive capacity. The risk to stocks from bycatch in coastal fisheries should be made by considering these particular stock estimates.

## Salmon bycatch risk

To be able to understand salmon bycatch risk, risk of exposure needs to be considered in combination with risk to stock. A study by Queiroz et al., (2019) estimated risk of exposure by modelling the overlap of sharks with fishing effort data. By combining information on salmon known presence at sea with the precise timing of their migration and fishing effort, an understanding of risk of exposure could be calculated similar to Queiroz et al., (2019). Since salmon can be caught by a range of gear types, a bycatch risk per gear type evaluation is initially required (e.g. Acou et al., 2021; ICES 2019), taking into consideration regional differences in gear use and salmon migration (risk of bycatch as they leave estuaries to risk of bycatch as they migrate north to their feeding habitat).

Through ICES WGBYC, annual PETS bycatch per unit effort (BPUE; number of fishing days monitored) is calculated (ICES 2022c). However, since bycatch probability distribution can be variable in space, according to gear type, and PETS density, Bycatch Evaluation and Assessment Matrix (BEAM) have been trialled (Appendix 3). BEAM considers bias-correction factors given known fisheries bycatch programmes, PETS abundance estimates, etc. (Appendix 3; ICES 2022c). Such a process could be adapted and trialled for salmon taking into consideration spatial-temporal variability at a finer resolution. ICES 2022c report does, however, note that for very low abundance species and species with low detectability (such as Salmon; Elliott et al., 2023a) the BEAM process may not be sufficiently robust.

Given the little understanding of bycatch risk at present, a combination of bycatch risk on stock (i.e. using the BEAM method) and exposure analysis (e.g. Queiroz et al., 2019) in space and time, would enable a finer understanding of salmon bycatch risk.

Summary of what we understand about migrations at sea
Post-smolt phase

One of the major limitations to understand bycatch of salmon at sea is lack of knowledge of their migration pattern at sea. The onset of emigration from river to the sea occurs in late March in Spain, and gradually starts later in the year further north with an onset in late July for smolts emigrating from rivers in northern Norway, Russia, Finland and northern Iceland (Otero et al., 2013). For post-smolts, a recent study by Gilbey et al. (2021) presented the geographic location of $>9000$ post-smolts sampled over nearly 25 years in the Northeast-Atlantic. The work identified a main migration route of post-smolts west of the British Isles in the period May-June and further north in the Norwegian Sea in June-August (Figure 2). A high proportion of individuals originating in southern NEAC among post-smolts sampled in the Norwegian Sea indicate that this is an important migration route for post-smolts from many European countries (Gilbey et al., 2021). Post-smolts from Iceland, Russia and Finland were however absent from the samples from the Norwegian Sea suggesting that individuals originating in these countries migrate elsewhere. A study of smolts tagged with archival tags and released in Iceland indicated that the estimated migration path was from spending the first summer as post-smolts west of Iceland, over the Icelandic continental shelf and in the Irminger Sea, to an eastward migration towards the ridge between Iceland and the Faroes during autumn (Gudjonsson et al., 2015).

Smolts from northern Norway, Finland and Russia enter the White Sea or the Barents Sea. The migration pattern in the Barents Sea is unknown, but eastward-going surface currents in the southern Barents Sea could transport post-smolts into the eastern Barents Sea (Russian territory). Due to the lack of knowledge, one must assume that post-smolts can migrate through any part of the Barents Sea from July and onwards. The migration pattern for smolts emigrating into the North Sea is also not known in detail and post-smolts could migrate through any part of the North Sea in the period April-July.

Figure 2. Catch per unit effort (CPUE) in targeted surveys for each $1^{\circ}$ latitude $\times 1^{\circ}$ longitude grid square containing at least one trawl. Points represent mean post-smolt captures per trawl within the grid unit. Small grey points represent grid squares with trawl coverage but no captures (Figure from Gilbey et al., 2021).

## Adults

Knowledge of migration patterns of salmon in the northeast-Atlantic after the first post-smolt phase (first summer and autumn in the sea) is limited. A recent study has described the annual migrations routes of kelt from several European countries, which were tagged and tracked with pop-up tags when leaving the rivers after spawning (Rikardsen et al., 2021; Figure 3a). Salmon from Denmark and middle part of Norway mainly migrated towards the polar front east of

Greenland, between Iceland and Svalbard. Salmon from northern Norway either migrated towards northwest and the region east of Greenland or northeast into the Barents sea. In contrast, salmon from Ireland, Spain and Iceland mainly migrated westward towards the Irminger Sea and the areas south of Iceland. The migration routes presented in Rikardsen et al., (2021) are supported by migration routes estimated in other tagging studies (Gudjonsson et al., 2015, Strøm et al., 2018). Furthermore, results from genetic assignment of origin of salmon caught as bycatch in mackerel fisheries south and east of Iceland indicated that the sea south and east of Iceland are important as feeding areas for migrating Atlantic salmon, particularly for salmon originating in the UK, Ireland, and southern Europe (Olafsson et al., 2016). The lack of adult Icelandic fish so close to Iceland was pointed out by the authors as an indication that Atlantic salmon from Icelandic stocks are using different feeding grounds. The results of tagging studies using codedwire tags conducted on Icelandic salmon stocks between 1967 and 1995 have indicated that there might be a difference in the migration routes used by stock from North and East part of Iceland compared to the south and west. Most of the recoveries north of the Faroes were 2SW tagged in northern and eastern Iceland, whereas recoveries in West-Greenland were recoveries from 2SW salmon tagged as smolts in southern and western Iceland. This pattern suggested that 2SW salmon from the south and west coast of Iceland tend to migrate west towards Greenland, whereas 2SW salmon from the north and east coast migrated to a large extend into the Denmark Strait and the Norwegian Sea (Isaksson et al., 2002). The historic commercial fishery targeting salmon in Faroes waters were further south during autumn than during winter (Jacobsen et al., 2012) (Figure 3b). Multi-sea winter fish dominated the catches taken in the Faroes fishery (O'Sullivan et al., 2022). Some sea winter salmon were also caught as bycatch during the IESSNS survey in the Nordic Sea (ICES 2022e), indicating that also the central Norwegian Sea is used a feeding area during summer.

Figure 3. a) Migration of post-spawning Atlantic salmon tagged in eight different geographical areas (figure from Rikarden et al., 2021), b) Recapture locations of tagged salmon during autumn (red dots, November-December) and winter (blue dots, January-April) north of the Faroes the years 1968-2000. The dividing line in a northwest-southeast direction was drawn by hand (figure from Jacobsen et al., 2012).

## Pelagic fisheries and potential for salmon bycatch

Pelagic fisheries are fisheries that target commercially important fish, such as herring and mackerel, that inhabit the water column (not near the seabed or shore), with specific gear types (e.g. purse-seine, midwater pelagic trawls, etc.; Appendix 4; He et al., 2021). As can be seen within Figure 1 (spatial fishing effort of pelagic fisheries by ICES divisions) and Appendix 2 - Figure A1
pelagic fisheries take place both within inshore and offshore waters (ICES 2022c). Large-scale pelagic fisheries which are at risk of bycatching salmon include mackerel, sardine, herring, blue whiting, capelin, and sprat (ICES 2005; ICES 2022e; Sumner 2015). Below major pelagic fisheries which are thought to overlap with salmon migration have been summarized (2.2.5.1-2.2.5.8).

Access to weekly catches from large pelagic fisheries in key locations for Northeast Atlantic stocks was analysed by ICES study groups in 2004 and 2005 salmon (ICES 2004, 2005). Here, SGBYSAL examined the disaggregation of commercial catch data of mackerel and herring within the Norwegian Sea, the norther of the North Sea and the northwest of Ireland and Scotland by ICES Division and standard week. While it was suggested that there were certain areas and times of concern for salmon post-smolt migration where there was potential overlap with commercial fishing activity, the catches were small at the time when the salmon were thought to move through these areas. Unfortunately, the SGBYSAL commercial pelagic activity dataset is not currently available post 2005, leaving doubt over the potential influence of shifts in the distribution and intensity of more recent fishing fleet activity.

It should be noted that "Discarding from pelagic fisheries is more sporadic than from demersal fisheries since target species are schooling fish which often have a low diversity in species and sizes (Borges et al., 2008; Ulleweit et al., 2010; ICES 2022c). Fish caught by these fisheries are taken straight below deck and frozen in large holding tanks due to the quantity of catch (Borges et al., 2008). Only a small and variable proportion of hauls are therefore sampled for bycatch (ICES 2004, 2005). Bycatch of smolts is particularly difficult to observe (because of their small size and the loss of scales), and variable according to the timing and location of the haul (ICES 2005). In 2015 the EU introduced landings obligations for small pelagic fish. This obligation has been generally effective since 2019 (ICES 2022b) and so bycatch within pelagic fisheries may now be easier to monitor." (text from ICES 2023a).
"In addition to bycatch recordings from observers on pelagic vessels, slippage (when part of the catch is released back out to sea prior to sorting) sometimes occurs. This sort of bycatch can be qualitatively recorded as it is released back to sea and species length and composition is determined by samples from the hold or from the following or previous haul (Borges et al., 2008). It is thought that slippage might be an important component of discards in pelagic trawlers but it is frequently not recorded due to estimation difficulties (e.g. ~3000 t of fish a year, mainly from the North Sea; Borges et al., 2008)." (text from ICES 2023a). Work under ICES Working Group for Technology Integration for Fishery-Dependent Data (ICES 2023b) have suggested new imagery methods to monitor slippage from pelagic vessels. It is, however, likely to be difficult to detect Salmon bycatch from such video images.
"Catch data from the Norwegian Sea can be combined with scientific survey data from the mackerel survey (IESSNS) in the region in July for the years 2010-2021. The probability to catch salmon, or the catch rates from the scientific survey, can be used to estimate the total potential bycatch for the mackerel fishery in the Norwegian Sea considering the temporal and spatial dynamics of both Salmon migrations and the commercial mackerel fishery. IESSNS trawl data are stored in the PGNAPES database at the Faroe Islands and are not available as open-access. The countries participating in this survey have nevertheless indicated that salmon catch data from trawl hauls can be made available for a study on salmon bycatch from pelagic trawling in the area" (text from ICES 2023a).

## Mackerel fishery

There is a substantial mackerel trawl fishery around Britain and Ireland during winter (Decem-ber-March). The fishing effort during spring (April-May), when most smolts in Southern NEAC leave the rivers, is however limited. The first period of the post-smolt migration does therefore not overlap in space and time with a large mackerel fishery (Figure 4). Mackerel migrate into the Norwegian Sea from June onwards, supporting a large trawl fishery in this region. Furthermore,
mackerel has expanded north- and westwards in recent years (Figure 5, Nøttestad et al., 2016), and the total landings of mackerel from this fishery have increased. In 2021, vessels from Russia, Iceland and Greenland landed more than 300000 t of mackerel, with most of the catches taken in the Norwegian Sea (ICES 2022e). This is a substantial increase from $\sim 54000 \mathrm{t}$ landed in this region in 2005 (ICES 2006). Norway and Faroe Islands also target mackerel in the Norwegian Sea, but these countries take most of the catches during autumn (August and onwards). A quality assured estimate is currently not possible due to lack of observations and samples from the fishery. A sampling programme at land-based freezing plant was initiated in 2011 to investigate salmon bycatch in the mackerel fishery (pelagic pair-trawls). Salmon were only observed in May and June ( 76 individuals among 31315 t of mackerel) although the fishery lasted until September (ICES 2012), probably reflecting a lower geographic overlap between the Faroes mackerel fishery and post-smolts later in summer. Similar screening of Icelandic mackerel landings in 2010, 2011 and 2012 resulted in 170, 233 and 48 salmon, respectively (Olafsson et al., 2016, ICES 2013a). Most of these individuals were sea-winter salmon, and the estimated bycatch was 5.5 salmon per 1000 t of mackerel caught in the 2010 - 2013 fisheries. The westerly distribution of mackerel, into Icelandic Exclusive Economic Zone (EEZ), continued from 2013 and salmon bycatch has been reported to the Directorate of Fisheries to be between five and 92 a year. However, in the most recent years the abundance of mackerel south and west of Iceland has decreased and since 2020, majority of the catch from the Icelandic fleet has been in international waters east of Iceland. The pelagic fishery close to Iceland is normally west of the main post-smolt migration route in the Norwegian Sea (Gilbey et al., 2021) but probably overlap with the feeding areas for sea-winter fish (see Jacobsen et al., 2012). Screening of Russian catches in June-August 2002 and 2003 in the central Norwegian Sea recorded a bycatch of 13 post-smolts and 30 sea-winter salmon among 11 560 t of mackerel (ICES 2005). Both Russian and Norwegian research surveys in the Norwegian Sea have substantial higher proportions of salmon among mackerel than estimated by screening commercial mackerel catches (ICES 2005, ICES 2022e). There is also a substantial autumn fishery in the North Sea and the southern Norwegian Sea, but the autumn fishery has a low spatiotemporal overlap with known post-smolt migration routes. There is however a potential overlap with sea-winter salmon feeding in these areas, but data on this issue is very limited.

Figure 4. Maps of total commercial catches of NEA-mackerel in 2021 per quarter of the year (Figure modified from ICES 2022e).

Figure 5. Catch of mackerel ( $t$ ) by year and rectangle. Catch by rectangle data do not represent the official catches and cannot be used for management purposes. In general, the total annual catches by rectangle are within $10 \%$ from the official catches (Figure retrieved from ICES 2022e).

## Norwegian Spring Spawning Herring

The main fishery take place during the 4th and 1st quarter of the year. The fishing fleet target NSSH in the Norwegian Sea during in October-December when herring migrate towards overwintering grounds, in December-January along the northern Norwegian coast or during the spawning migrations in February-March (Figure 6), and both pelagic trawl and purse-seines are applied. Bycatch of salmon can occur, but the risk is probably low. The western location of the herring fishery during late autumn can overlap with historic feeding grounds for adult salmon in northern Faroes (Jacobsen and Hansen 2001) and eastern Icelandic Waters. There is only a limited fishery for NSS-herring during April-June, in the period when the majority of post-smolt migrate along the Norwegian coast or in the Norwegian Sea. There is a trawl fishery during JulyAugust east of Icelandic and north of Faroe Islands (Figure 6), which may spatially overlap with both post-smolts and sea-winter salmon. The SGBYSAL report (ICES 2004) describes an incident with 200 sea-winter salmon caught among 800 t of herring in the Norwegian Sea southwest of Svalbard in august 2002. There has not been a fishery for herring in the northern Norwegian Sea in recent years.

Figure 6. Total reported landings (ICES estimates) of Norwegian spring-spawning herring in 2020 by quarter and ICES rectangle. Landings below 10 t per statistical rectangle are not included. The landings with information on statistical rectangle constitute 99.2\% of the reported landings. Figure taken from ICES 2021b.

## Icelandic summer-spawning herring

The distribution of Icelandic summer-spawning herring has shown a large variation between periods which is reflected in the changes of catch locations. For example, the herring fishery 2021/2022 took place in offshore waters west and east of Iceland whereas majority of the catches in 2007-2010 were caught in shallow waters inside Breiðafjörður in the west of Iceland (Figure 7; MFRI 2022). The fisheries for Icelandic summer-spawning herring are done by purse-seines and usually is an autumn fishery (September-December) but continues into January or February in some years. The risk of overlap is therefore limited for post-smolt because their migration happens outside the timing of the fisheries. There might be an overlap with sea-wintering fish, however, the risk varies between years due to the shift in distribution patterns mentioned above.

Figure 7. The distribution of catches of Icelandic summer-spawning herring given in tonnes for different periods from 1991-2021. For the years 2007-2010 the distribution inside Breiðafjörður is shown in the right-bottom corner. Figure from MFRI 2022.

## North Sea herring and adjacent areas

Herring fisheries occur over a wide spatial area (Figure 8). The largest fishery is within the North Sea with an estimated Spawning Stock Biomass of 1.35 million tin 2021. A Celtic Sea and Channel autumn and winter stock also exists with landings of just 34000 t (ICES 2022f). The Irish Sea autumn stocks has a spawning stock biomass of just under 40000 t , and a west coast of Scotland herring (ICES division 6) spring and autumn fishery also occurs (ICES 2022f).

The North Sea herring pelagic trawl and purse-seine fishery takes place late April, May, and June. The fishery occurs in northern parts of the North Sea and can potentially have bycatch of both post-smolt and returning adult salmon from British, Swedish, Danish, German, and Norwegian rivers. The fishery during summer is limited, but there is an autumn fishery in central and western parts of the North Sea from August to December. The risk of salmon taken as bycatch in the autumn fishery is limited but cannot be excluded due to salmon potentially feeding in the North Sea during autumn and winter. The fishery for North Sea herring during winter is very limited.

Figure 8. Catch by statistical rectangles of North Sea herring each quarter of the year in 2021. Figure taken from ICES 2022f.

## Capelin

Barents Sea capelin: Landings of capelin in the Barents Sea has large interannual and decadal variation due to the large fluctuation in stock size. During the 70 s and early 80 s, annual landings were within the range 1-3 million $t$ (ICES 2021c) and the fishery had two seasons: August-October and January-April. Due to several collapses of the stock, annual landings have ranged from 0 to 360000 t since year 2003 and there is no longer an autumn fishery. The fishery has in recent years been carried out in the Barents Sea close to the coast off northern Norway (Figure 9), but the fishery was completely closed in 2016-2017 and in 2019-2021. Bycatch of sea-winter salmon have occurred in the capelin fishery (ICES 2004). The fishery has limited risk of bycatch of salmon due to the relatively small total landings in most years, but there may be a spatio-temporal overlap with salmon feeding in the Barents Sea. There is anecdotal information about salmon taken as bycatch in the winter capelin fishery.

Icelandic capelin: The distribution of capelin around Iceland has changed following warming of the ocean both for the adult spawning stock as well as for the immature stock. Both juveniles and adults have moved west and north towards Greenland from 2000 (Bardarson et al., 2021). The fishing of capelin in Icelandic Waters is mostly taking place in winter during January - March and the distribution of the catch has been moving to the north along with the changes in stock distribution, but the catch follows the spawning migration and begins east of Iceland and then moves along the southern coast and ends on the western coast of Iceland (Figure 10, Singh et al., 2020). The capelin fishery has a risk of bycatch of salmon but may be limited due to timing which does not coincide with post-smolt migration. Capelin is, however, a common prey-item for salmon, and recent tagging of kelts from various countries (Rikardsen et al., 2021 see figure 3) might be indicating that post-spawning salmon from southern Norway and from Denmark migrate up to the coast of Eastern-Greenland and overlap with the feeding grounds of Icelandic capelin during autumn - early winter. Whether the salmon follows the capelin on their spawning
migration south and would therefore be subjected to fisheries of the Icelandic fleet is unknown. Bycatch reports from capelin fisheries of the Icelandic fleet are less common than the bycatch of the mackerel fleet.

Figure 9. The geographic distribution of Norwegian capelin catches in the Barents Sea the years 2012-2018. Circles represents purse-seine catches while crosses represents trawl catches, and colour coding represents the catch month (Jan-uary-blue, February-green, March-pink, April-red; Figure produced by Are Salthaug).

Figure 10. Distribution of catch intensities from the winter capelin fisheries separated by months (1-3; representing January - March) and two time periods (1993-2002 and 2003-2018). Position of the centre of gravity of weekly catches is indicated by numbers corresponding to calendar weeks. Figure from Singh et al., 2020.

## Horse mackerel

Horse mackerel are fished in the North Sea, the English Channel, west of Scotland and Ireland and in the bay of Biscay. There is a trawl fishery potentially overlapping with migrating postsmolts west of France and Ireland and in the English Channel in the period April-June (Figure 11). The total landings in 2021 was $\sim 93000 \mathrm{t}$ with $\sim 8000 \mathrm{t}$ landed in the period April-June, which makes it a small fishery compared to several of the other pelagic fisheries in the North Atlantic (ICES 2022e).

Figure 11. Maps of total commercial catches of horse mackerel in 2021 per quarter of the year (Figure modified from ICES 2022e).

## Blue whiting

The risk of salmon occurring as bycatch in the blue whiting fishery was evaluated by SGBYSAL (ICES 2004) and WGNAS (ICES 2017). The main fishery target spawning blue whiting southeast of the Faroes Islands and west of Scotland and Ireland during the period January-April (Figure 12). During January-April, blue whiting are fished with pelagic trawl at 250-600 m depth. The risk of bycatch of salmon in this winter-fishery has previously been evaluated to be low (ICES 2004, 2017). Blue whiting is also fished with pelagic trawl at the feeding grounds in the Norwegian Sea during late spring and summer. This is often a mixed fishery targeting other pelagic fish, but the fishery can also be a single-species fishery targeting blue whiting. The fishery in the Norwegian Sea increase in years when a lack of coastal state agreements on how to share quotas restricts some nations to fish blue whiting at the spawning grounds. A directed trawl fishery for blue whiting in the Norwegian Sea have a higher risk of catching salmon as bycatch due to the spatio-temporal overlap with both post-smolt and sea-winter salmon, although trawling is normally not done at the surface. SGBYSAL did not report any observations of salmon taken as bycatch in the blue whiting fishery (2004), but there was a catch of 5 kg salmon among a commercial catch of blue whiting taken within the Icelandic EEZ in 2015 (ICES 2017).

Figure 12. Blue whiting catches per quarter 2020. The catches on the map are based on logbook data and constitute 98.9 $\%$ of the ICES estimated catches. The total catches and percentages shown on each panel are also based on logbook data, and therefore deviate slightly from the ICES estimated catches pr. quarter. The $\mathbf{2 0 0} \mathbf{m}$ and $\mathbf{1 0 0 0} \mathbf{m}$ depth contours are indicated in blue (Figure modified from ICES 2021b).

## Anchovy and sardine

Southern anchovy and sardine fisheries occur in the Bay of Biscay (ICES division 8.a, b and c) and northern Atlantic Iberian waters (9.a). The sardine fishery also extends north to southern Celtic seas and the English Channel (ICES divisions 7). Both fisheries consist of purse-seine and pelagic fleets (ICES 2022g).

The Bay of Biscay anchovy purse-seine fleet mainly takes place in autumn, whereas the purseseine Basque fishery mainly operates in spring. The pelagic trawlers largely operate during the second half of the year (July-October), but with less catches. In 2021 catches were 27982 t which has reduced following the anchovy fishery closure (2005-2019). Anchovy catches in 2021 within division 9.a was estimated at 17837 t . This Iberian anchovy fishery is almost exclusively harvested by purse-seine fleets (ICES 2022g).

The sardine fishery takes place in Celtic Seas (7.a, b, c, f, g, j, k), English Channel (7.d, e, h) and in Bay of Biscay (8.a, b, c). The Spanish sardine purse-seine fishery (8.c) takes place during March and April and in the fourth quarter of the year. Sardine catches have declined from 8000 t in the late 90 s to just under 6000 t in 2021. In France (ICES divisions 8.a-b) just over 20000 t of sardine were landed in 2021 and mainly from coastal waters (< 10nm from the coast) from purse-seine fisheries. Highest catches are usually during summer, but winter catches can also be important (ICES 2022g).

## Greenland halibut, cod, and redfish in East Greenland

The pelagic fisheries in East Greenland have been absent in the two most recent years since Atlantic mackerel has moved further east in the North Atlantic. Offshore bottom trawling for cod, redfish, and Greenland halibut (Reinhardtius hippoglossoides) is unlikely to have salmon bycatch. Salmon were never caught in bottom-trawl surveys.

## North Sea sandeel

Sandeel fisheries occur throughout their range with the main fishery occurring in the North Sea between $1^{\text {st }}$ of April and the end of July. Sandeel populations have declined in recent years after peak catches in the late 1990s reaching to more than 1 million $t$ (primarily from Norwegian and Dutch vessels). After a period of declined effort in the early 2000s, effort in recent years has increased again with the fourth highest CPUE of the time-series occurring in 2021 (ICES 2022f). Sandeels are primarily caught by pelagic trawls with a small mesh ( $<32 \mathrm{~mm}$ codend) but also by demersal trawls (ICES 2022h). In recent years the fleet size and distribution has changed to fewer but larger vessels (>40m; ICES 2022f, 2022h). The spatial distribution of this fishery is variable from year to year (Figure 13; ICES 2022f).

Figure 13. Sandeel in ICES Subarea 4 and Div. 3.a. Catch by ICES rectangles 2006-2021. Area of the circles is proportional to catch by rectangle (ICES 2022f).

## The overlap with Coastal fisheries

"Since salmon migrate out from and back to their natal rivers, bycatch from coastal fisheries can occur, and have been primary observed in gillnet fisheries targeting fish such mullet, sea bass, and sea trout (Sumner, 2015; Elliott et al., 2023a). Adult salmon are more likely to be caught than smolts by static gear due to their size, and because return timings can span a larger proportion of the year (Gillson et al., 2022)" (paragraph from ICES 2023a).

Here we define coastal fisheries as fisheries that take place within 12 nm of countries. This is because stricter nation-specific fisheries restrictions occur within 12 nm of each country's coast allowing only certain non-native vessels to fish within these waters (Historic fishing rights). Within this limit, a range of fishing activities can take place by country based as well as foreign vessels depending on each country's rules and regulations.

Few studies exist on the risk of salmon bycatch from coastal fisheries. This is because reporting of coastal bycatch can be cumbersome for smaller ( $<12 \mathrm{~m}$ ) vessels, and they are not required to have VMS installed. A distribution modelling study by Elliott et al., (2023a) used imperfect detection from different fishing gear types from the French fisheries observer programme covering vessels $>12 \mathrm{~m}$ and ICES divisions 3.a, 4.b-c, $7 . d-h, 8 . a-b$. From this study, a higher gear capture was found from static fishing gear types (i.e. gillnets) followed by pelagic trawls (i.e. midwater pelagic trawls and midwater otter trawls; Figure 14). It should be noted that there are differences in fisheries, gear use, and onboard observer effort between countries (Ifremer, 2021; Cloatre et al., 2021; UK Data coordination group, 2022). Inshore VMS are now being enforced for vessels under 12 m and so monitoring of coastal fishing effort in future years will be more easily accessible.

Figure 6.1 (1) from WGBYC 2022 indicates potential coastal fisheries by métier level 3 gear categories (Appendix 4) which can be cross-verified with finer spatio-temporal scale fishing from GFW courser gear categories in Appendix 2. For the risk of bycatch to be considered, temporal coastal fisheries bycatch risk needs to be considered given the migration of salmon. Finer scale monthly VMS fishing effort per métier level 3 gear categories would, however, help better identify fisheries which overlap in space and time with salmon migration. Critical periods to look at are between April and June for smolts with more southerly stocks migrating earlier than northerly stock. Between May and July for returning adults, between March and May for MSW returning adults (more southerly stocks migrating earlier than northerly populations). For 1SW fish migrating back to sea following spawning, migrations occur from late winter to early spring (Gilbey et al., 2021; Rikardsen et al., 2021).

Figure 14. Salmon bycatch detectability from a distribution model containing French fisheries observer data covering waters in ICES divisions 3. a, 4.b-c, 7.d-h, 8.a-b (modified from Elliott et al., 2023a).

## Country specific coastal fishing summary

Iceland: Ocean fishery for salmon in Icelandic Waters was banned by law in 1932. However, prior fishing rights for salmon at five costal locations at the west coast of Iceland were operated until 1997 when a terminating buy-out agreement was accepted. Since that time, no legal fishery for salmon has been in operation. Coastal fishery for seatrout and sea-run Arctic charr are operated at few locations around the Icelandic coast. The fishing time is from $1^{\text {st }}$ of April through to September and the weekly fishing hours are 84 from Thursday morning at 10AM to Friday evening at 10PM. There are strict regulations on allowable fishing gear such as mesh size ( 40 mm knot to not), the thread thickness limit is set at $0,4 \mathrm{~mm}$, and the total length limit is 50 m with a depth of 2.5 m . This is to minimize the risk of adult salmon bycatch. Release of salmon is obligatory for
both dead and life fish. This is also the regulation for salmon taken as bycatch in other fisheries. Despite these strict regulations, bycatches can happen and are in some cases reported to the $\mathrm{Di}-$ rectorate of Fisheries.

Norway: Norway has a long coastline with a diverse fleet targeting a variety of species. The use of gillnets with mesh size larger than 32 mm (knot to nearest knot) above 3 m depth is prohibited to avoid bycatch of anadromous species. The use of gillnets in close vicinity to river mouths are for the same reason also illegal. The coastal gillnet fishery targeting species such as cod, saithe, monkfish and hake is normally carried out with bottom nets at $>30 \mathrm{~m}$ depth. Longlines are applied in the coastal fishery targeting the same species as the gillnet fishery. The risk of catching salmon at the longline or gillnet fishery is relatively small, although such bycatch has occurred (ICES 2017 and this report).

There is a small-scale purse-seine fishery within Norwegian fjords targeting pelagic species. The coastal fishery for mackerel (Figure 4), horse mackerel and herring (Figure 6) is carried out in autumn, although sporadic catches are taken throughout the year, and therefore have limited spatio-temporal overlap with both post-smolts and returning adult salmon. The coastal fishery for sprat is also carried out in autumn as its prohibited until $31^{\text {st }}$ of July. The coastal purse-seine fishery for saithe is carried out in spring-autumn and can potentially overlap in time and space with salmon in the Norwegian coastal zone. There are unverified reports of bycatch of salmon in the coastal purse-seine fishery for saithe and sprat (pers. comm and regional reports by the county governor). Bycatch in these fisheries may in some years overlap with late returning salmon which can remain in fjords and wait for increasing river discharge levels.

UK: Most of the UK's fleet comprises of $<10 \mathrm{~m}$ vessels ( $>4000$ vessels), with the Northern Irish and Scottish vessels have the most $>10 \mathrm{~m}$ vessels. Nonetheless larger vessels ( $>24 \mathrm{~m}$ ) hold up to $65 \%$ of the fleet's capacity. Landings of pelagic, demersal and shellfish species occurs in both inshore and offshore waters within UK waters (MMO, 2021).

UK - England and Wales: Very little information exists on salmon bycatch in English and Welsh observer data, but salmon bycatch from the English and Welsh offshore stratified random sampling programme of vessels $>7 \mathrm{~m}$ have been recorded by gillnets and demersal trawls. Although salmon at sea is not specifically targeted in England and Wales, landings collated data indicate captures from a range of gear types (static nets, pots, lines, demersal and pelagic trawls) since 2009.

Marine recreational fisheries are an important economic activity in English and Welsh waters, but they can have impacts on fish stocks (Hyder et al., 2021). Sea angling surveys began in 2016 to meet DCF requirements using a method described in UK DCF technical report (2016; EU DCF report 2021). In the England and Wales an estimated 437000 sea anglers were reporting in 2019 (Hyder et al., 2021). Since 2018 zero salmon have been recorded to be kept (Hyder et al., 2021). Unreported catch within recreational sea angling is unknown.

UK - Scotland: In addition to both inshore and offshore pelagic and demersal fisheries, a small net fishery targeting sea trout operates in Scotland.

UK - Northern Ireland: The coastal fisheries around N. Ireland are dominated by crustacean fisheries inclusive of potting/trapping for Cancer pagurus and Homarus gammerus and bottom trawling for Nephrops norvegicus. These fisheries offer virtually no chance of salmonid bycatch. The only notable inshore pelagic fishery in N. Ireland is a small-scale coastal fishery for herring (Clupea harengus) operated opportunistically along the coastline of County Down in the Irish sea Analysis of records for this fishery indicate that, when undertaken, it is operated in autumn (c. Sep-Nov) and employs gillnets to target herring. The timing of this fishery is outside the local smolt emigration window (April-June) and therefore unlikely to capture smolts or post-smolts as bycatch. No records of bycatch are available.

Unavailable country-coastal level information: Information about coastal fisheries in Portugal, Netherland, Germany, Belgium, East Greenland, Denmark, France, Ireland, Spain, Sweden, Russia, and Faroes was not available at the time of meeting but, would be required for a complete risk assessment.

## Report on Effectiveness of Monitoring

## What other monitoring happens that might detect salmon bycatch?

Within this section knowledge of existing monitoring methods (Table 1) are outlined. Note that these are not exhaustive but information which was available at the time of completing this report. It is also important to keep in mind that salmon and sea trout are frequently confused.

Table 1. Monitoring methods provided in the $\mathbf{2 0 2 2}$ data call-template and their suitability for inclusion in bycatch assessments as considered by WGBYC (ICES 2022c).

|  | Monitoring <br> Method | Summary |
| :--- | :--- | :--- |
| SO | At-Sea Ob- <br> server | Data collected by independent observers using appropriate protocols for quantifying bycatch <br> are currently considered by WGBYC to be the most reliable source of data for the calculation of <br> bycatch rates across the full range of sensitive taxa for inclusion in detailed bycatch assess- <br> ments. |
| PO | Port Ob- <br> server | Data collected by independent observers in port are not currently considered reliable enough <br> by WGBYC for the calculation of bycatch rates for inclusion in detailed bycatch assessments, <br> though they may have value for highlighting bycatch occurrence in fisheries with no other <br> monitoring. |
| EM | Electronic <br> Monitoring | Data collected with electronic monitoring systems with appropriately placed cameras and suit- <br> able species identification methods are currently considered by WGBYC to be reliable for calcu- <br> lating bycatch rates for inclusion in detailed bycatch assessments. |
| VO | Vessel Crew <br> Observer | Data collected by fishers following specific sampling protocols are currently considered by <br> WGBYC to be moderately reliable for calculation of bycatch rates, particularly if data accuracy <br> can be validated against independent monitoring data from the same fishery. |
| OB | Logbooks | Data recorded by fishers as part of mandatory bycatch reporting in official logbooks are cur- <br> rently considered by WGBYC to be unreliable for calculation of bycatch rates and inclusion in <br> detailed bycatch assessments (see Basran \& Már Sigurõsson 2021). Logbook data may have <br> value for highlighting bycatch occurrence in fisheries with no other monitoring and/or for sen- <br> sitive fish species that are permitted for sale. |
| OTH | Other unspecified monitoring methods, e.g., interviews with fishers, are currently considered <br> by WGBYC to be generally unsuitable for the calculation of bycatch rates for inclusion in de- <br> tailed bycatch assessments as underlying biases are difficult to evaluate and estimate. |  |

## Country-specific monitoring programmes:

East Greenland: There have been reports that people in Tasiilaq catches a few salmon when jigging for cod during winter from the sea ice, but the local fishery for cod, Greenland halibut and char is insignificant.

France: In 2011, a synthesis of coastal salmon bycatch in the Bay of Biscay (Basque-Landes coast) was conducted using several sources of information (at sea observations, reporting system, market sales data) gathered from 2000 to 2001 and then from 2005 to 2010 (Morandeau \& Caill-Milly 2011). Salmon were not a target species for this fleet, according to observers at sea and logbook analysis, but they were occasionally caught in small quantities. Only gillnets were used to catch salmon, accounting for less than $2 \%$ of the total catch of the observed vessels ( $18-200 \mathrm{~kg}$ ) and $0.1 \%$ of the total catch of all observations. Coastal vessels are likely to have a higher proportion. In
fact, because it is not a mandatory marketing method, data from the onshore-market network are only partially representative of actual catches (direct sales are possible). Marine recreational fisheries occasionally catch salmon, but their proportion of the total annual catch remains small (less than $1 \%$ ). It is also important to keep in mind that salmon and sea trout are frequently confused. In addition, France has an onboard observer programme (ObsMer) which has existed since 2003, where approximately $4 \%$ of vessels are boarded and recordings of bycatch are undertaken.

Ireland: Official fisheries statistics from the Irish Marine Institute from the Irish sea, Celtic Sea and Aran grounds regions, ICES Subdivision 27.6 and 27.7 , show no reports of salmon caught as bycatch. All coastal salmon target fisheries ceased from 2006. Salmon caught as bycatch must be reported if they end up in the discard sample, however there are currently no records of any bycatch/discard observations in Irish demersal and pelagic fisheries. The frequency of salmon being caught as bycatch is believed to be exceedingly low and as such may explain the lack of reporting in national demersal and pelagic discard databases. Unreported catch within recreational sea angling is unknown.

Norway: The fishery for anadromous fish is managed by the Norwegian Environment Agency, and salmon caught at sea is therefore not a part of the Norwegian legislation regulating the commercial fishery and sales of marine fish. Hence, salmon caught as bycatch in marine fisheries do not need to be reported to the marine fishery sales organizations. Furthermore, bycatch is not the focus when monitoring commercial catches from the pelagic and coastal fishery, although bycatch is one of several criteria used when performing a risk assessment of fisheries. Such risk assessment can lead to fishing activity being prohibited in restricted geographic areas and periods. It was not possible to retrieve data on landings screened for bycatch within the deadline of this report.

Some salmon caught as bycatch in other marine fisheries are sold to, and thereby being registered by, the marine fish sales organizations. This includes salmon caught in the licenced bag- and bend-net fishery as well as salmon caught as bycatch when targeting other marine fish. After removing the salmon that most likely were caught in the licenced salmon fishery, a total of 175 salmon caught at sea were registered by marine fish sales organizations in the period 2013-2022 (Table 2). The majority of these (100 individuals) were caught by gillnet, and these individuals were taken throughout the year and along the entire Norwegian coastline. For the other gear categories, the landed salmon was mostly caught in coastal waters off southern Norway. It is reasonable to assume that a large proportion of the salmon caught along the Norwegian coast is escaped farmed salmon as especially escaped adults tend to remain in the coastal region after escaping the pens (Skilbrei et al., 2015).

Table 2. Salmon caught at sea and sold through the Norwegian sales organizations for marine fish in the period 20132022.

| Fishery | Region | Number | Months |
| :--- | :---: | :---: | :---: |
| Purse-seine | Southwestern Norway | 20 | Aug-Dec |
| Gillnet | Entire Norway | 100 | Jan-Dec |
| Trawl |  |  |  |
| (shrimps) | Southern Norway | 12 | Mar-Jul |
| Lines | Entire Norway | 14 | June-Sep |
| Traps | Southern Norway | 29 | Mar-Aug |

Spain: Since 2010, bycatch statistics only show two sales of salmon (two fish) in the Asturian markets, both corresponding to year 2011. There is no other reported salmon bycatch.

Sweden: Official fisheries statistics from the Swedish Agency for Marine and Water Management (SWaM) from the Kattegat and Skagerrak regions, ICES Subdivision 20-21, show very small amounts of salmon caught as bycatch. Since all salmon target fisheries ceased from 2015, all reports (max. 79 kg ) after this date are presumed to be bycatch, however, not officially reported as bycatch. It is also unknown in which fishery these salmon were caught as bycatch. The gear reported for salmon was gillnets, traps and fykenets.

The Swedish Agency for Marine and Water Management (SWaM) has the overall responsibility for Swedish implementation of the EU's fisheries control in Sweden. SWaM are responsible for controlling the fish that is caught, landed, imported, exported, transported, and sold in Sweden. This is conducted, among other things, by monitoring quotas and effort (fishing days at sea), document control, landing control, transport control and decisions on fishing stops. However, documentation of bycaught salmon, especially on the west coast of Sweden, is not prioritized. Catch reporting is mandatory but the reported catch statistics need setter follow-up and bycatch statistics needs improvement. The term 'bycatch' is not consistently used and can refer to landed non-target species, 'discard' (fish thrown back in the sea) or bycatches of mammals or birds. Salmon can also be reported as regular catch, even when you fish for other species. Since 2015 there are no commercial licenses for salmon fishery in the sea, hence all caught salmon after 2015 should be considered bycatch.

The EU has decided that vessels over 12 meters must report their activities electronically. The aim is to get real-time information of fishing activities, to ensure sustainable fishing and to carry out effective supervision. Every commercial fisher is responsible for having the technology and permits required according to EU directives and Swedish law.

SWaM do not have a specific monitoring programme that specifically applies to bycatch. Targeted bycatch studies exist in Sweden's DCF WP (SLU Aqua - Swedish University of Agricultural Sciences), called Discard sampling. In the Discard sampling, SLU Aqua measures catches on-board fishing boats, with the aim to quality assure catch reports to SWaM, by comparing the catch composition when SLU is present on-board with the reported catch composition when SLU is not present, to better estimate bycatch on all trips. Observer trips have occurred on longline and gillnet vessels between 2017-2019.

UK (England \& Wales): England and Welsh onboard sampling programme undertakes stratified random sampling (by region, fishing methods and occasionally by vessel size) of vessels $>7 \mathrm{~m}$. Vessels specializing in fishing methods, fishing in foreign ports, unsafe for observers or smaller than 7 m are excluded from the sampling framework. Each observer collects information for each sampled haul, specifically: gear type and mesh size, tow duration, shot and haul position, species catch composition and quantity of the landings and discards in the catch. In cases where it is not possible to process all the samples, the measured volume is estimated relative to the total catch to get a raising factor and estimate the total catch. Specifically, during each trip numbers at length are raised to the haul and then to the whole trip, which can result in rare species such as some diadromous fishes being underrepresented.

Commercial fisheries reporting of catch returns through logbooks by licensed netsmen is mandatory. To address concerns about the reliability of catch return data, and to comply with international obligations to reduce the levels of illegal and unreported catch, a carcass tagging scheme was introduced in 2009. Furthermore, fisheries are required to report the monthly numbers and total weights of salmon and grilse taken (MMO et al., 2021).

An onshore market sampling programme also exists for demersal, crustacean, and pelagic species. The programme estimate length and or age composition of landed components. The sampling framework comprises of auction ports and ports of sale, and days of the year. Very small ports and ports where access is denied are excluded. None-response and refusal to provide
information are also recorded (UK Data coordination group, 2022). No, or very little, salmon has been recorded from this sampling plan but may be interesting to monitor. Such a sampling programme exists in other EU nations for PETS species.

UK (Scotland): All salmon taken as bycatch by this fishery are recorded by fishers in logbooks and reported to MSS. This bycatch is published as part of the Scottish governments official Salmon and Sea Trout fishery statistics (https://data.marine.gov.scot/dataset/salmon-and-sea-trout-fishery-statistics-1952-2021-season-reported-catch-district-and-method). Marine Scotland Science (MSS) oversees an at-sea scientific observer scheme for sampling biological information on catch under the (https://www.gov.uk/guidance/data-collection-framework). This observer scheme is carried out jointly by MSS and Scottish Fishermen's Federation (SFF) observers. This is a statistical survey which covers around $1-2 \%$ of $>10 \mathrm{~m}$ demersal otter trawl and seine fishing trips per year with most effort on demersal species ( $91 \%$ ) to provide parameters for stock assessments and fishery management (MMO, 2021).

The scientific observers obtain a sample of unwanted catch at the time of sorting, from which they obtain biological information. This information is used in the statistical estimation of weights and numbers of unwanted catch by species, area, and fishery. These estimates for each calendar year are submitted to ICES for use in stock assessments. Any salmon found in the sample would be measured and recorded. The data are stored in Marine Scotland's database.

The planned number of fishing trips on which scientific observers conduct sampling each year is as follows: 36 whitefish fishing trips ( $36 \mathrm{MSS}, 52 \mathrm{SFF}$ ). In recent years, due to covid restrictions, these plans have not been attainable, and in practice, the number of fishing trips has been substantially reduced, but is hoped the scheme will be fully operational by the end of 2023.

An additional at-sea observer scheme, the UK Bycatch Monitoring Programme (BMP), is conducted by the Sea Mammal Research Unit (SMRU). This is a monitoring programme originally designed to monitor cetacean bycatch but has since been extended to cover other protected species, including salmon. The programme targets UK fisheries considered to have high bycatch rates, including longlines and gillnets. Monitoring of pelagic fisheries was reduced due to the lower risk of bycatch observations. The data are stored in databases held by SMRU and are submitted to WGBYC data calls as required.

Scotland also has an onshore sampling design for pelagic landings (mackerel, herring, and blue whiting with horse mackerel and sprat). For this process a bucket of unsorted fish from the vessels tanks is sampled per landing. Fish length, otoliths, sex, and maturity are recorded for the first three individuals from each cm length class.
UK (Northern Ireland): No monitoring for salmonid bycatch in the coastal herring fishery. It is conducted outside the local smolt migration window and unlikely to capture salmon.

## Bycatch of PIT-tagged Atlantic salmon in pelagic fisheries detected at fish processing plants

Northeast-Atlantic mackerel and Norwegian Spring spawning herring have been tagged with passive integrated transponder (PIT) tags since 2011 and 2016, respectively. Antennas at commercial fish processing plants automatically detect tagged fish, but these antennas can also detect PIT-tagged salmon among commercial catches of pelagic fish. This requires the detected PIT-tag ID's to be crosschecked against lists of PIT-tags applied to wild salmon. Automatic detections of PIT-tags can provide new knowledge on bycatch of salmon in pelagic fisheries (ICES 2017).
Locations of tagged smolt - 560787 Norwegian smolts were tagged with PIT-tags during the period 2014-2021 and released in rivers or river estuaries. The smolts were released during the smolt migration period for the respective rivers, which is in the period April-June for rivers along western and middle Norway (Vollset et al., 2021). The tags applied to salmon vary with the
institutions in charge of the tagging and include both full-duplex (FDX) and half duplex (HDX) tags of $12,12.5,16,22,23$ or 32 mm length. Most of the tags were 23 mm HDX tags. Relatively few salmon were tagged with $12.5,22 \mathrm{~mm}$ or 32 mm tags, and these tags are considered equivalent to 12 mm or 23 mm tags in this report. In addition, PIT-tagged smolts are also released from Scotland and Ireland although with a smaller number of individuals and over fewer years than in Norway. These data were not included in the analyses presented here.

Detection of PIT-tags in fish processing plants - The tags applied to mackerel and NSS-herring are full-duplex 23 mm tags. The tag detection antennas in commercial fish processing plants can always detect these tags, but the ability to detect various other tags are determined by tag size, duplex and manufacturer and vary between plants. There is in general a higher probability to detect FDX compared to HDX, and 23 mm tags compared to 12 mm tags.
Screened commercial catches of pelagic fish - Data on all commercial catches of mackerel, NSSherring and North Sea herring handled by Norwegian fish processing plants during 2014-2021 were delivered by "the Norwegian Fishermen's Sales Organization for Pelagic fish". In addition, data on mackerel landings in 2014-2021 screened by other processing plants capable of detecting PIT-tags were also retrieved (ICES 2022e). The total annual biomass of screened fish is summarized in Table 3 considering the ability of the respective fish processing plant's abilities to detect different PIT-tags. The catch location of each commercial landing per ICES statistical rectangle is given in Figure 15-18.

Table 3. Annual total landings of mackerel, North Sea herring and NSS herring ( t ) and the biomass screened for fish tags at the fish processing plants (Full duplex (FDX) or half duplex (HDX) $\mathbf{1 2}$ or $\mathbf{2 3} \mathbf{~ m m}$ tags). A) Mackerel b) North Sea Herring c) Norwegian Spring Spawning herring.

Figure 15. The catch locations of mackerel screened for PIT-tags for the years 2014-2021. The colour scaling represents total biomass of screened fish (t) per rectangle.

Figure 16. The catch locations of North Sea herring screened for PIT-tags for the years 2014-2021. The colour scaling represents total biomass of screened fish (t) per rectangle.

Figure 17. The catch locations of Norwegian Spring Spawning herring screened for PIT tags for the years 2014-2021. The colour scaling represents total biomass of screened fish ( $t$ ) per rectangle.

Detections of PIT-tagged salmon - Three tagged salmon were automatically detected among the screened commercial catches of pelagic fish. Two individuals were post-smolts caught during their first summer at sea while the last individual had spent $21 / 2$ years in the sea. Two individuals were taken as bycatch in the mackerel fishery while one individual was caught in the fishery for North Sea herring. The first fish was tagged in spring 2017 at "Etneelva" with a 23 mm FDX tag. The individual was recaptured on the 16 October 2019 in the mackerel fishery. Possible recapture locations are close to the Norwegian coast or west in the North Sea close to Scotland (Figure 18). The second fish was tagged at "Vosso" in spring 2018 with a 23 mm HDX tag. It was recaptured further west in the North Sea on 26 June the same year. The individual was recaptured in the fishery for North Sea herring where the fishing gear was either purse-seine or pelagic trawl. The third fish was tagged at "Årdalselva" in spring 2015 with a 23 mm HDX tag and recaptured on 8 July the same year in the fishery for mackerel. Possible recapture locations are in close vicinity of the home river (Figure 17). The individual was caught in a coastal fishery among 20-25 tof mackerel.

Fish nr 1

Fish nr 3

Fish nr 2

the type of PIT-tags used for salmon, the detection probability of salmon tags in fish processing plants and the catch location and period of screened pelagic landings. The most common PITtags used for salmon, 12 mm half-duplex tags, have a low probability of being detected by PITrecording antennae in fish processing plants. Furthermore, the fishery targeting mackerel in the Norwegian Sea in June-August, where the risk of bycatch of salmon is assumed to be high, is not delivering catches to the fish processing plants that can detect PIT-tags. It can also be mentioned that large salmon, especially those taken in smaller catches of pelagic fish, will most likely be removed directly by the fishermen. The method is therefore more reliable for post-smolt caught as bycatch in large pelagic trawl or purse-seine catches.

## Risk

## Risk of exposure matrix in pelagic fisheries (not risk to the stock)

Risk of exposure in coastal fisheries could not be undertaken here because information on fishing seasons was lacking. A risk of exposure matrix in pelagic fisheries, where data were available, is provided in Table 4. This is the WGNAS qualitative evaluation of the risk based on the incomplete information presented above (2.2.5).

Levels of risk exposure were defined as follows:

- Low risk: no bycatch, limited overlap of salmon presence in space, depth and time with a particular fishery;
- Medium risk: some bycatch recorded or potential overlap of salmon presence in in space, depth and in time with fisheries;
- High risk: multiple recorded bycatch and known overlap of salmon presence in in space, depth and in time with fisheries.

Levels of uncertainties were defined as follows:

- Low certainty: no existing information;
- Medium certainty: occasional bycatch observation or assumed low spatio-temporal overlap between the pelagic fishery and known migration routes and feeding areas for salmon.
- High certainty: multiple and regular recordings through official scheme.

Table 4. Pelagic fisheries risk of exposure matrix from literature. Note, this is not a comprehensive matrix as quantitative analysis would be required for this. Risk to stocks has not been considered either. Inshore fishing activities has not been added to this as a result of too little information at present to complete.

| Country | Species | FAO subcategory | Period | Main ICES Division | Risk | Certainty level ( $\mathrm{H}, \mathrm{M}, \mathrm{L}$ ) |

## Other matters of interest

## Targeted bycatch information

Dedicated targeted data collection programmes may be able to provide more information on bycatch of PETS species than non-targeted data such as from observer programmes. This was observed in the case of the EU IUCN critically endangered, red-listed European sturgeon (Acipenser sturio). From French fisheries observer data 11 A. sturio were recorded from 2003-2021 (Elliott et al., 2023b), but from a targeted A. sturio bycatch database (STURWILD; Centre for Aquaculture, Fisheries, and the Environment in New Aquitaine 142 - CAPENA, National Committee of Maritime Fisheries and Marine Fish Farming - CNPMEM, French 143 National Research Institute for Agriculture, Food and Environment - INRAE) just over 300 observations at sea from 2012 to 2021 were recorded within a reduced area than that from the fisheries observer data (Charbonnel et al., 2022a; 2022b).

## Bycatch risk analysis

The French Office for Biodiversity have undertaken a bycatch risk analysis for all Habitat Directive listed species. Together with the French, a UK Fisheries Industry Scientific Partnership (FISP) project proposal (Minimising Interactions between protected Diadromous Fish and marine quota Fisheries (MInDiFF)) has been submitted to DEFRA to improve understanding of bycatch risk of diadromous fish. For this project, UK and French fisheries-dependent and -independent data are planned to be used to model the habitat of diadromous fish during the marine phases of their life cycles (Elliott et al., 2023a). Outputs from the species habitat models, in
conjunction with a gear-specific bycatch matrix derived from the fisheries-dependent data (Acou et al., 2021) will be developed and used to quantify bycatch risk using gear-specific fishing effort data (Quemmerais-Amice et al., 2020; Toison et al., 2021). Upscaling such a project could provide more detailed information on bycatch risk and salmon distribution.

## eDNA analysis

Since salmon bycatch data are difficult to fully understand, in part due to very low abundances, and their non-shoaling behaviour relative to other pelagic species, even a small amount of bycatch may impact their populations (Elliott et al., 2023a). eDNA analysis could therefore be used to monitor bycatch and improve understanding of salmon migratory pathways (Atkinson et al., 2018; Bracken et al., 2018; Jenrette et al., 2023).

## Gaps and future developments

If NASCO wishes further precision, the following should be undertaken by the member countries and appropriate agencies:
i. Improve understanding of post-smolts and adult salmon migration route in time.
ii. Move towards more quantitative bycatch risk analysis through:

- An analysis of risk of exposure, e.g. using information on salmon probability of presence across their migratory paths and modelling this with fishing effort data from higher risk gear types (taking into consideration both coastal and pelagic fishing effort) at an ICES rectangle and monthly scale to match the migratory timings (e.g. Queiroz et al., (2019)).
- Analysing risk to the stock (e.g. trialling and modifying ICES WGBYC BEAM method on selected fishing gears in selected regions).
iii. Recommendation to ICES that salmon be included in the list of WGBYC species and data calls, and that WGBYC contributes to future salmon advice. If salmon is included, it is recommended that a salmon experts join WGBYC. Work with WGRFS to monitor catch and mortality of salmon sea angling. Links between WGRFS and WGBYC already exist (WGRFS latest report).
iv. Standardize salmon bycatch monitoring programmes across countries, including minimum standards for data recording and reporting.
v. Ensure descriptions of the sampling effort and sampling plan relative to total effort for the various fisheries per country (e.g. number of observed vessel-day/total days fished, per fishery/year) are easily accessible.
vi. Improve screening for salmon. Basic priorities for screening include:
- Where not already recorded, salmon bycatch should be monitored, data collected and reported by country;
- More salmon identification guidance is needed (confusions occur with the sea trout (Salmo trutta));
- Minimum data to be collected are: date, fishery, catch location, number of salmon bycatch, fork length (preferably) and/or weight;
- The screening of discards from factories should be explored (recommendation from ICES 2004) by having close collaborations with factories operators.
vii. Later priorities for full and effective screening include:
- data to be collected on: date, vessel size category, gear type and target species, effort, catch location, number of salmon bycatch (including zeros in known salmon bycatch fisheries), fork length and weight, screen and record tag number (if present), scale samples;
- The screening of commercial catches on board commercial fishing vessels in pelagic (recommendation from ICES 2004, 2023a) and gillnet fisheries (recommendation from ICES 2023a);
- For fisheries that are of relevance to potential salmon bycatch, protocols should be established for screening herring and mackerel fisheries, as these are likely to require special screening methods (recommendation from ICES 2004).
viii. Trial eDNA sampling with salmon detection analysis both scientific and commercial pelagic trawls ensuring uncertainty is taken into consideration. This could be undertaken as part of observer data collection and thereby being of use to detect other PETS.

## Glossary of terms used in this annex

- Bycatch $=($ defined at the start $)$
- Offshore = 12 to 200 nm which is within the Exclusive Economic Zone as defined under UNCLOS
- Coastal $=0$ to 12 nm which equates to FAO's definition of territorial seas
- Inshore $=<6 \mathrm{~nm}$ from the coast. This definition is used since in $<6 \mathrm{~nm}$ from the coast only vessels from their own nations (where allowed) can fish in these waters.
- High seas $=>200 \mathrm{~nm}$
- Gear codes have used FAO definitions and gear categories (see Appendix 4)

## Appendix 1. Summary of SGBYSAL 2004

"The major pelagic fisheries in the Norwegian Sea, the North Sea and areas west and south of UK and Ireland were described and potential areas of interaction were identified based on time (quarters) space (ICES statistical rectangles) and gear type in use in the various fisheries (ICES 2004c). Information on salmon movements at sea were used to indicate that the period of potential overlap in the Norwegian Sea mackerel fishery was probably limited to a relatively short period, centred around the latter half of June and early July, confirming the need for access to weekly disaggregated catch data to fully assess potential bycatch. Disaggregated data for landings to the UK and Germany enabled a closer study of mackerel and herring fisheries in the western (VIa) and northern North Sea areas (IVa) per week and statistical rectangle. Possible areas of interception were detected also in these areas (ICES 2004c).

A model for estimating progress in time and space of post smolt cohorts in the Norwegian Sea, based on data on distribution from research surveys was also examined and projected northward with estimated progression speeds of salmon. The Study Group recommended that with further development and using appropriate data, this model could form a useful tool to assess the risk of post smolts being intercepted by commercial fisheries in the area of passage.

A review of available information on detection of salmon during screening of catches by various countries was also carried out, revealing small but consistently occurring bycatches, mainly in various types of trawl fisheries. The advantages and constraints of various methods of screening pelagic catches for bycatch of salmon were evaluated and it was concluded that observer-based onboard screening programmes were the most effective method.

Analytical methods to estimate post-smolt bycatch in commercial fisheries were also explored, using the Norwegian Sea mackerel fishery as the only example where salmon catch rate data had been obtained. Based on quarterly catch data, the overlap between post smolts and the fisheries in the Norwegian Sea appeared high, but the absence of disaggregated data (by week and statistical rectangle), impeded an assessment of the true overlap of post smolts with the fisheries.

In the absence of data on intercalibration between research catch methods and commercial catch methods, the Study Group concluded that the best method presently available would be based on direct observation on board commercial fishing vessels according to agreed protocols. Thus, estimates would be based on consistent gear types and fishing methods and would not depend on transferability of data from research catches. However, it was stressed that disaggregated catch data for week and standard rectangle for the areas in question was still a priority."

## Appendix 2. Global fishing watch fishing effort information

Global fishing watch (GFW) data are measured in fishing hours per day and the data are provided at $100^{\text {th }}$ of a degree (Kroodsma et al., 2018b). Figures A1 - A5 are calculated by using the total fishing effort per $0.2 \times 0.2$ decimal degrees per month, year and GFW gear category. The mean monthly fishing effort was then calculated across the years the data were collected (2012 and 2022) by gear categories which are most relevant to salmon bycatch. Mean monthly fishing effort was calculated to gauge potential overlap with salmon migratory pathways and fishing effort by gear category. Results appear to match summarized data from ICES fisheries overviews and mixed fisheries advice
(https://www.ices.dk/advice/Fisheries-overviews/Pages/fisheries-overviews.aspx\#:~:text=Fish-eries\ overviews\ summarize\ the\ services\ derived\ from\ fishing,methods\ being\ used \%2C\%20and \%20how\%20stocks\%20are\%20managed).

## Appendix 3. ICES WGBYC Bycatch Evaluation and Assessment Matrix (BEAM) criteria classification

### 5.3.4 The BEAM: criteria classifications

Table 5.2. Categories and classifications contained within the beam.

## Appendix 4

FAO gear types and categories (He et al., 2021) and EC (2010/93/EU) gear classes. Gear categories from Elliott et al., 2023b have been added since when trying to assess bycatch by gear categories FAO subcategories do not separate demersal from pelagic gears. Grey cells indicate no information from that data source.

[^0]:    ICES INTERNATIONAL COUNCIL FOR THE EXPLORATION OF THE SEA CIEM CONSEIL INTERNATIONAL POUR L'EXPLORATION DE LA MER

[^1]:    ${ }^{1}$ With regard to ToR 1.1, for the estimates of unreported catch the information provided should, where possible, indicate the location of the unreported catch in the following categories: in-river; estuarine; and coastal. Numbers of salmon caught and released in recreational fisheries should be provided.
    ${ }^{2}$ With regard to ToR 1.2, ICES is requested to include reports on any significant advances in understanding of the biology of Atlantic salmon that is pertinent to NASCO.

[^2]:    ${ }^{3}$ In the responses to ToRs 2.1, 3.1 and 4.1, ICES is asked to provide details of catch, gear, effort, composition and origin of the catch and rates of exploitation. For homewater fisheries, the information provided should indicate the location of the catch in the following categories: in-river; estuarine; and coastal. Information on any other sources of fishing mortality for salmon is also requested. For ToR 4.1, if any new surveys are conducted and reported to ICES, ICES should review the results and advise on the appropriateness of incorporating resulting estimates into the assessment process.
    ${ }^{4}$ In response to ToR 4.2, ICES is requested to provide a brief summary of the status of North American and North-East Atlantic salmon stocks. The detailed information on the status of these stocks should be provided in response to ToRs 2.3 and 3.3.

[^3]:    ${ }^{1}$ Includes other internal tags (PIT, ultrasonic, radio, DST, etc.)
    ${ }^{2}$ Includes Carlin, spaghetti, streamers, VIE etc.

[^4]:    ${ }^{1}$ Includes other internal tags (PIT, ultrasonic, radio, DST, etc.)
    ${ }^{2}$ Includes Carlin, spaghetti, streamers, VIE etc.

[^5]:    b.v.3) If the assessment has been moved to a Category 2-5 approach in the past year con-

    N/A, cat 1 stocks sider what is necessary to move back to a Category 1 and develop proposal for the appropriate benchmark process.
