Abstract

The very hot summers of recent years have led to an increase in the number of large forest fires in Europe. We investigated four large fire sites in Brandenburg and Saxony (Germany) up to 4 years after the fires with a focus on studying the post-fire fungal communities. In this context, we documented two species of *Agaricomycetes* associated with mosses, which are common but particularly emerge on burnt areas, i.e., *Arrhenia bryophthora* sp. nov. and *Bryopistillaria clavarioides* sp. nov. The former is an agaric with omphalinoïd habit that causes the dieback of the common moss *Ceratodon purpureus*; the latter is a clavarioid fungus associated with either *Ceratodon purpureus* or another common moss, *Funaria hygrometrica*. Both fungal species appear to be restricted to recently burnt areas and have otherwise not been observed on or in close vicinity of these mosses. Herein, we describe these fungi macro- and micromorphologically as well as on a molecular basis and discuss their taxonomic position and potential lifestyles.

Keywords Bryophily · *Arrhenia bryophthora* · *Bryopistillaria clavarioides* · Forest fire · *Ceratodon purpureus* · *Funaria hygrometrica*

Introduction

Burnt areas represent special, spatially and temporally limited habitats that are colonized by a specialized fungal community (Dix and Webster 1995). These species are generally considered to be highly adapted but weak in competition (El-Abyad and Webster 1968b). After a fire, the topsoil in particular is poor in microorganisms and alkalized to a certain extent (El-Abyad and Webster 1968a). The rapid colonization mechanisms of fire sites by phoenicoid fungi have been intensely documented and discussed since the second half of the twentieth century and four general hypotheses have so far been proposed: dispersal hypothesis, dormancy hypothesis, heat tolerance hypothesis, and body snatchers hypothesis (Matheny et al. 2018). However, none of these hypotheses

has been sufficiently verified, and it seems plausible that fungi can pursue different strategies (Matheny et al. 2018; Filialuna and Cripps 2021).

In the absence of freshly burnt areas, certain species of the genera *Sphaerospora*, *Wilcoxinia*, *Geopyxis*, and *Peziza* s.l. are endophytically associated and/or form mycorrhizas with different tree species and may only fruit after their host is damaged by wildfires (Hughes et al. 2020; Pulido-Chavez et al. 2021). The rather common species *Pholiota carbonaria* and *Plicaria carbonaria* follow a typical saprotrophic lifestyle as decomposers of dead plant biomass (Matheny et al. 2018; Kouki and Salo 2020). However, it was shown that the range of trophic lifestyles is broader than originally assumed (Raudabaugh et al. 2020). In addition to saprotrophy, *P. carbonaria* can interact with *Polytrichum commune*, a moss that also occurs on burnt areas (Raudabaugh et al. 2021). In the case of *Plicaria* spp., it has recently been reported that they have endophytic phases in mosses (Raudabaugh et al. 2020). Moreover, members of the genera *Anthracoïbia*, *Geopyxis*, *Peziza*, *Tricharina*, *Psathyrella*, and *Cotylidia* seem to be endophytically associated with various bryophytes as well (Raudabaugh et al. 2020; Korotkin et al. 2018).

Thus, many groups of fungi are dependent on post-fire mosses quickly colonizing burnt areas. Due to the perfect

light and nutrient situation on such areas, these bryophytes can reach high abundancies of individuals, for example, *Funaria hygrometrica* and *Ceratodon purpureus* (Esposito et al. 1999; Sim-Sim et al. 2004).

In addition to phoenicoid fungi, bryophilic associations are not uncommon in some fungal families. For instance, the *Hygrophoraceae* (*Agaricales*) show a broad spectrum of interactions with phototrophic partners. They range from species that form lichens (*Dictyonema*, *Lichenomphalia*) to ectomycorrhizal species that live in mutualistic symbiosis with trees (*Hygrophorus*); others are endophytic biotrophs in grasslands (*Hygrocybe* s. l.) or develop strong associations with bryophytes as in the case of *Arrhenia* (Halbwachs et al. 2018; Redhead et al. 2002b; Lodge et al. 2014; Lawrey et al. 2009). The *Rickenellaceae* (*Hymenochaetales*) consist of various genera that are strictly associated with mosses (as parasites, commensals, or symbionts), e.g., *Bryopistillaria*, *Muscinipta*, *Sphagnomphalia*, *Rickenella*, and *Loreleia* (Redhead et al. 2002a; Korotkin et al. 2018).

Until the recent major forest fires in the Northern Hemisphere, such exceptional habitats could only rarely be studied, especially in Europe (Moser 1949; Butin and Kappich 1980). One reason for this is the strict forest fire policy of European countries, which leads to the removal of dead wood and prohibits the development of smaller fire areas in the wild. For this reason, phoenicoid fungi have only rarely been found in European countries (Knudsen and Vesterholt 2012; Dämmrich et al. 2016). On the other hand, after the great fires of the last years, it can be assumed that still undiscovered species live in these specific and (so far) underrepresented habitats. Against this background, we have mycologically examined four large forest fire areas in Germany (Brandenburg and Saxony) over the last 6 years. Among the collected fungi, two members of the *Agaricomycetes*, *Hygrophoraceae* and *Rickenellaceae*, are described herein.

Material and methods

Morphological study

The basis of this study is the investigation of large forest fire events in Saxony and Brandenburg, Germany (for details see the examined samples below). The fires took place in the years 2018, 2019, and 2022 (Brandenburg) and 2022 (Saxony). Sampling was carried out from 2019 on in periods of higher precipitation and in the winter half-year, when the weather was favorable for fungal fruiting.

Fresh specimens were photographed in the field, collected, morphologically examined and documented, and finally, dried and stored. In addition, the surrounding plants and mosses were recorded. The microscopic examination and documentation of the morphological characteristics of

fresh and dried specimens were done with a Zeiss AXio1 light microscope with $\times 100$, $\times 400$, and $\times 1000$ magnification in combination with a Canon EOS 60D, digital camera, or a Bresser microscope equipped with a Toupcam SPC-MOS05000KPA. The microscopic measurement was done manually with a measuring eyepiece (Zeiss, Germany) or digitally in CorelDRAW2019 or in ToupView. Microscopic drawings are based on real microscopic photographs traced in CorelDRAW2019. Type specimen are deposited at Herbarium Senckenbergianum Görlitz (GLM).

Molecular genetic study and phylogenetic reconstruction

DNA of the samples was extracted using the E.Z.N.A.® Plant DNA Kit or the REDEExtract-N-Amp Kit (Sigma-Aldrich) in 1:5 dilution. The primer pairs ITS1F/ITS4, ITS1F/ITS4B, and LR6/LR0R (White et al. 1990; GARDES and BRUNS 1993) and the DreamTaq Green PCR Master Mix (2x, Thermo Scientific™) or YourTaqPolymerase (in case of Touchdown PCR) were used to amplify and sequence the partial 28 s rDNA (large subunit, LSU) and internal transcribed spacer (ITS) barcoding region. The polymerase chain reaction was setup in an Eppendorf 5341 Mastercycler. The reaction involved initial denaturation at 95 °C for 2 min, followed by 35 cycles in series of denaturation at 95 °C for 0.5 min, annealing at 52 °C for 0.5 min, and extension at 72 °C for 1 min, with a final step of one cycle at 72 °C for 10 min to final extension. Subsequently, the PCR products were purified using the PCR Purification Kit-Column Kit (Jena BioScience) or sent directly to Eurofins (Germany) for further processing. The purified PCR products were sequenced in both directions at LGC Genomics GmbH (Berlin) or at Eurofins Genomics. The resulting chromatograms were quality-checked and edited in Geneious Prime 2023.2 (Kearse et al. 2012).

The newly generated sequences (ITS and LSU) were compared and identified with entries in GenBank using a blastn search (Altschul et al. 1990). Selected sequences of related species from GenBank and UNITE (Nilsson et al. 2019) and own generated sequences were concatenated and aligned using Clustal Omega 1.2.2 (Sievers and Higgins 2021) implemented in Geneious 2023.2. The alignments were carefully checked and edited manually; ambiguous regions were masked and not used for phylogenetic analysis. All newly gathered sequences were submitted to GenBank under accession numbers OR912523–OR912545 (or listed in Table 1).

Maximum Likelihood (ML) phylogenetic analysis was performed using RAxML 8.2.11 (Stamatakis 2014) implemented in Geneious 2023.2, applying the rapid bootstrapping algorithm with 1000 replicates. Four nucleotide partitions (ITS1, 5.8S, ITS2, 28S) were set, and the GTR

GAMMA I substitution model was applied, in addition to one binary partition (indel characters) that was set to default. The Bayesian Inference (BI) phylogeny was carried out using MrBayes 3.2.6 (Huelsenbeck and Ronquist 2001) implemented in Geneious 2023.2. Four gamma categories were used with the GTR substitution model and the invgamma rate variation. The Markov Chain Monte Carlo were set to 1,000,000 generations, sampling every 1000th generation. The first 20% of the trees was discarded as burn-in. For the remaining trees, a 50% majority rule consensus phylogram with posterior probabilities as nodal supports was computed. Clades with bootstrap support above 95% for ML and 0.95 for BI are considered highly supportive. Phylogenetic trees were edited in Geneious 2023.2 and in Corel Draw (v21.0.0.593 Corel Corporation).

Results

Phylogenetic analysis

Result of the phylogenetic analysis based on sequences of the ITS and 28S rDNA (LSU) region from *A. bryophthora* and members of the *Hygrophoraceae* Lotsy selected from GenBank and UNITE is depicted as RAxML tree in Fig. 1. *Serpulomyces borealis* and *Amylocorticium cebennense* were selected as outgroup.

The aligned matrix contained 1814 unique nucleotide position features (262 ITS1, 157 5.8S, 353 ITS2, and 1041 28S) for the entire dataset of 93 specimens. Generated phylogenetic ML and BI trees had similar topological structures (compare Fig. 1 and S1).

The genera of *Hygrophorineae*, i.e., *Cantharocybe Chromosera*, *Chrysomphalina*, *Haasiella*, and *Lichenomphalia*, each form statistically well-validated clades. Sequences of *Arrhenia bryophthora* cluster in a statistically well-validated clade (BP/BI: 100/1) that is basally located in *Arrhenia* s.l., indicating that this species belongs to that monophyletic clade. However, this clade is only moderately supported statistically (BP/BI: 51/0.96).

Arrhenia s.l. comprises species with different ecological affiliations. These are categorized as follows: The *gerardiana/bigelowii* clade and the *telmatiaea/philonotis* clade include facultative or obligate sphagnophilic species and one lignicolous species. The *obatra/velutipes* clade (plus two unknown and possibly undescribed species), the *rustica*

Fig. 1 RAxML tree combining selected ITS and LSU-sequences from the *Hygrophorineae* Aime, Dentinger & Gaya including *A. bryophthora* BP and BI values less than 50 and 0.75, respectively, are omitted. Bold lettering indicates species' sequences generated in this study, and red font indicates the newly described species. Pictograms mark presence or absence of clamps

0.6

Fig. 2 RAxML tree combining selected ITS and LSU-sequences of the *Rickenellaceae* Vizzini (*Hymenochaetales*) related to *B. clavarioides*. BP and BI values less than 75 and 0.75, respectively, are omitted. Bold lettering indicates species' sequences generated in this study, and red font indicates the newly described species

Fig. 3 In situ photographs of *Arrhenia bryophthora*; IHI-23Arr4-KS52 (A), IHI-23Arr1-KS2 (B), and GLM-F137751—type (C, D), scale bars 1 cm. Photos A. Karich

Fig. 4 Typical (GLM-F137751—type (A)) and exceptional (IHI-23Arr1-KS2 (B)) basidiospores and basidia of *Arrhenia bryophthora*; scale bars 10 μm

clade, and the *obscuratalacerosa* clade include species with unknown but possibly biotrophic ecology. Biotrophic species are represented by the *bryophthora* clade and species within *Arrhenia* sensu stricto (including the type species of the genus *A. auriscalpium*).

A RaxML tree based on ITS and LSU sequences from *B. clavarioides* and allied sequences of representatives from the *Rickenellaceae* in GenBank and UNITE is depicted in Fig. 2. The aligned matrix contained 2322 unique nucleotide position features (267 ITS1, 163 5.8S, 247 ITS2, and 1645

28 s) for the entire dataset of 86 specimens. Generated phylogenetic ML and BI trees had similar topological structures (compare Fig. 2 and S2).

Sequences of *Bryopistillaria clavarioides* generated in this study and three additional sequences of environmental samples form a distinct and well-supported clade that is closely related to specimen-sequences of *Bryopistillaria sagittiformis* from Olariaga et al. (2020) displaying sequence similarities in ITS sequences from 89.25 to 90.42%. Sequences of both species form a well-supported clade in the *Rickenellaceae* RaxML tree (BP/1: 90/1).

The RAXML tree contains six monospecific genera, i.e., *Globulicium*, *Canthrarellopsis*, *Sphagnomphalia*, *Muscinupta*, *Blasiphalis*, and *Ginnsia*. Together with the genera *Contumyces* and *Alloclavaria*, all these clades are well supported (BP/BI:100/1). Samples of the genus *Cotylidia* form two separate clades, each being well supported (BP/BI: 100/1). One includes *C. undulata*, the genus' type species, and hence is accounted as *Cotylidia* sensu stricto. And the second phylogenetically separate clade groups around *Cotylidia diaphana*. These results indicate that *Cotylidia* is polyphyletic and should be divided. However, this is beyond the scope of this work.

Moss-associated species of the genus *Rickenella* form a well-supported clade. *R. minuta*, that was recently discovered to have an ectomycorrhizal relation to *Notofagaceae* in Argentina builds a sister clade to those *Rickenella* with strict bryophilic relation (Korotkin et al. 2018). The entire *Rickenella* clade is only moderately well supported (BP/BI:75/1).

Taxonomy

Arrhenia bryophthora Karich, Jarling, R. Ullrich, sp. nov.

Mycobank number: 851246

Type: GLM-F137751 – Germany, Zeithain, Gohrischheide, Plot 3, 13,33206 E 51,43189 N, 95 m asl., fire site in forest with *Pinus sylvestris* and *Betula pendula*, on and in between post fire moss *Ceratodon purpureus* and possibly *Funaria hygrometrica* and causing their dieback, 23rd of March 2023, leg. A. Karich, R. Ullrich and R. Erlacher.

Etymology: From ancient Greek βρύον (brúon, “moss”) and φθορά (phthorá, “destruction”).

Diagnosis: Small brown agaric with omphalinoid habit growing on old fire sites in association with *Ceratodon purpureus* and causing its dieback. Being distinct from other similar species in *Arrhenia* s.l. by the absence of clamp connections.

Macromorphology (Fig. 3a–d): Basidiocarps small, omphalinoid. Cap 4–10 mm broad, distinctly translucently striate when fresh, striae and in the center dark, chestnut to coffee brown (RAL 040 40 30 and RAL 040 30 20, respectively), between striae lighter, maple syrup brown (RAL 060 60 40), strongly hygrophanous when drying,

glabrous to slightly scaly when young (scales hygrophanous), margin crenulate. Lamellae falcate-decurrent, distant, L=14–18 with 1–2 lamellulae, maple syrup brown. Stem 6–12×1–1.5 mm, of cap color, finely pruinose in fresh specimen, turning glabrous at age, basally with whitish mycelium when young. No specific smell and taste. Spore print white.

Micromorphology (Fig. 4a, b): Basidia solely four-spored to predominantly two-spored, 25–30×6–8 μm, clampless. Basidiospores heteromorphic, cylindrical, dacryoid to subglobose, with distinct apiculus, (6)6.5–8(9)×3.5–5(5.5) μm, ave. 7.1–8.1×3.7–4.1 μm, $Q=1.4–2.4$ ave. 1.8–2.0 an exceptional specimen bearing subglobose to globose spores with deviating measurements, 7–9×4.5–7.5(8) μm ave. 7.9×5.7 μm, $Q=1.1–1.7(1.8)$ ave. 1.4 (IHI-23Arr1-KS2). Trama and cutis in pileus and stipe composed of 3–9 μm broad hyphae with partially fine to distinct incrusting pigmentation. Lamellar trama irregular, hyphae 2–9 μm broad, frequently distinctly incrustated and often branched. No cystidia observed. No structures amyloid or dextrinoid. No clamps observed.

Habitat (Fig. 5a–e): Growing on old fire sites (0.5 to 4 years postfire) solitarily or in clusters in between the dioicous moss *Ceratodon purpureus*, also observed near *Funaria hygrometrica* and *Marchantia polymorpha*, causing the dieback of the surrounding *C. purpureus*, being evident by brownish, circular, about 15 cm diameter large spots on the moss surface (compare Fig. 5). Fruit body formation was observed from September to May, mainly in November and March.

Distribution: So far, only known from four localities in Brandenburg and Saxony, Germany.

Additional specimens examined:

20201007-V312 – Germany, west of Luckenwalde, Felgentreu, Plot V3, 13.041819 E, 52.087368 N, 65 m asl., fire site on former *Pinus sylvestris* forest with few *Betula pendula*, on and between post fire moss *Ceratodon purpureus* causing its dieback, 7th of October 2020, leg. J. Neuendorf, T. Pilz-Hunter.

20201125-U913 – Germany, west of Luckenwalde, Felgentreu, Plot U9, 13.039827 E, 52.089232 N, 65 m asl., fire site on former *Pinus sylvestris* forest with few *Betula pendula*, on and between post fire moss *Ceratodon purpureus* and possibly *Funaria hygrometrica* causing their dieback, 25th of November 2020, leg. W. Linder, A. Schaepe, S. Hutter.

20210310-J209 – Germany, east of Treuenbrietzen, Frohnsdorf, Plot J2, 12.936418 E, 52.043814 N, 95 m asl., *Populus-Betula* succession on fire site on former *Pinus sylvestris* forest, cleared, plowed, and reforested with *Pinus sylvestris*, on and between post fire moss *Ceratodon purpureus*, causing its dieback, and healthy *Polytrichum piliferum*, 10th of March 2021, leg. W. Linder, A. Schaepe.

Fig. 5 Brownish circular spots on the moss surface of *Ceratodon purpureus* caused by *Arrhenia bryophthora* (A); basidiocarps of *A. bryophthora* (IHI-23Arr3-KS49) constantly growing inside these spots (B–E); scale bars 5 cm. Photos A. Karich

A. Karich, R. Ullrich and R. Erlacher.

IHI-23Arr2-KS48 – Germany, Zeithain, Gohrischheide, fire site in forest with *Pinus sylvestris* and *Betula pendula* (fire in summer 2022), Plot 1, 13.33253 E, 51.41907 N, 95 m asl., on and in between post fire moss *Ceratodon purpureus* and possibly *Funaria hygrometrica* and causing their die-back, 23rd of March 2023, leg. A. Karich, R. Ullrich and R. Erlacher.

IHI-23Arr3-KS49 – Germany, Zeithain, Gohrischheide, fire site in forest with *Pinus sylvestris* and *Betula pendula* (fire in summer 2022), Plot 4, 13.33253 E, 51.41907 N, 95 m asl., on and in between post fire moss *Ceratodon purpureus* and possibly *Funaria hygrometrica* and causing their die-back, 23rd of March 2023, leg. A. Karich, R. Ullrich and R. Erlacher.

IHI-23Arr4-KS52 – Germany, Zeithain, Gohrischheide, fire site in forest with *Pinus sylvestris* and *Betula pendula* (fire in summer 2022), Plot 4, 13.33148 E, 51.4124 N, 95 m asl., on and in between post fire moss *Ceratodon purpureus* and possibly *Funaria hygrometrica* and causing their die-back, 23rd of March 2023, leg. A. Karich, R. Ullrich and R. Erlacher.

***Bryopistillaria clavarioides* Karich, Jarling & R. Ullrich, sp. nov.**

= *Clavaria tenuipes* ss. Kajan & Grauwinkel 1987

Non *Clavaria tenuipes* Berk. & Broome 1848

Mycobank number: 851247

Type: GLM-F137752 – Germany, Zeithain, Gohrischheide, Plot 2, 13.33372 E 51.42659 N, 95 m asl., fire site in forest with *Pinus sylvestris* and *Betula pendula* (fire in summer 2022), on and in between post fire mosses *Funaria hygrometrica* and *Ceratodon purpureus*, 23rd of March 2023, leg. A. Karich, R. Ullrich and R. Erlacher.

Etymology: Referring to the macromorphological similarity with species of the genus *Clavaria* L.

Diagnosis: Small to medium sized club shaped fruit body with whitish to cream color. Occurring on old fire sites in association with *Funaria hygrometrica* and *Ceratodon purpureus*. Distinct from other clavarioid fungi by its phylogenetical association to *Bryopistillaria sagittiformis*. Distinct from the later by its larger size and different habit and lifestyle.

Macromorphology (Fig. 6a–f): Basidiocarps clavarioid (club shaped) 10–25(30) \times 1–3 mm, whitish to yellowish-crème (RAL 9003 to RAL 1012) to almost pale yolk-yellow (RAL 1002). Sterile stem about 1/5 to 1/4 (1/3) of entire club, glabrous and with somewhat glassy surface, demarcated from fertile head which is broadened, glabrous or wrinkled with age and with a dull surface, tips tan when drying. No specific smell and taste. Spore print white.

Micromorphology (Fig. 7a, b): Basidia 16–26 \times 5–6 μ m, four or two (one) spored, clampless. Basidiospores subglobose, ellipsoid to oblong dacryoid, often adhering to each other in packages of two or four, with distinct apiculus, inamyloid, (4.5)5.0–6.0(6.5) \times 2.5–3.5 μ m, ave. 5.6 \times 3.0 μ m, Q = (1.4)1.7–2.2 ave. 1.90 in typical predominantly four spored specimens (GLM-F13775/IHI-23RClav2-KS29), and 7.5–9.0(9.5) \times (2.5)3.0–3.5(4) μ m, ave. 8.1 \times 3.3 μ m, Q = 2.1–3.2 ave. 2.5 μ m in predominantly two spored specimens (IHI-23RClav1-KS2). Stipiticutis consisting of 4–7 μ m broad cylindrical and parallel directed hyphae. Trama in stipe and hymenium consisting of 5–20 μ m wide,

subirregularly directed hyphae, often constricted at the septa. No cystidia observed. All structures without iodine reactions. All septa clampless.

Habitat: Growing on up to two years old fire sites in between *Funaria hygrometrica* and *Ceratodon purpureus*. Sometimes, the mosses concomitant dieback was observed. Fruiting observed in spring and autumn. Attempts to obtain cultures from shed spores and fresh basidiocarps unsuccessful.

Distribution: Known from Europe and two soil samples from North America.

Additional collections examined:

IHI-23RClav1-KS2 – Germany, Nationalpark Sächsische Schweiz, Richterschlüchte—Krinitzgrab, 14,27467 E 50,89607 N, 450 m asl., fire site in forest with *Picea abies*, *Larix decidua*, *Pinus sylvestris*, and *Fagus sylvatica* (fire in summer 2022), on and in between post fire mosses *Funaria hygrometrica* and *Ceratodon purpureus*, 4th of April 2023, leg. A. Karich, R. Ullrich, F. Salzsieder and R. Erlacher.

IHI-23RClav2-KS29 – Germany, Zeithain, Gohrischheide, Plot 1, 13,33253 E 51,41907 N, 95 m asl., fire site in forest with *Pinus sylvestris* and *Betula pendula* (fire in summer 2022), on and in between post fire mosses *Funaria hygrometrica* and *Ceratodon purpureus*, 23rd of March 2023, leg. A. Karich, R. Ullrich and R. Erlacher.

20190906–002 – Germany, east of Treuenbrietzen, Frohnsdorf, 12.905322 E, 52.037015 N, 95 m asl. *Populus-Betula* succession on fire site on former *Pinus sylvestris* forest (fire in summer of 2018), on and between post fire moss *Ceratodon purpureus* causing its dieback, September 6th 2019, leg. R. Jarling, J. Ehrlich.

20201118-F618 – Germany, east of Treuenbrietzen, Frohnsdorf, Plot F6, 12.918541 E, 52.042959 N, 95 m asl., *Quercus*-plantation with *Populus*-succession on fire site (fire in summer of 2018) on former *Pinus sylvestris* forest, on and between post fire moss *Ceratodon purpureus* causing its dieback, 18th of November 2020, leg. A. Schaepe, W. Linder.

20201118-FF39 – Germany, east of Treuenbrietzen, Frohnsdorf, Site F, 12.917358 E, 52.042550 N, 95 m asl., *Quercus*-plantation with *Populus*-succession on fire site (fire in summer of 2018) on former *Pinus sylvestris* forest, on and between post fire mosses *Ceratodon purpureus* and *Funaria hygrometrica* causing their dieback, 18th of November 2020, leg. A. Schaepe, W. Linder.

20201119-D126 – Germany, east of Treuenbrietzen, Frohnsdorf, Plot D1, 12.916197 E, 52.040119 N, 95 m asl., *Populus*-succession on fire site (fire in summer of 2018) on former *Pinus sylvestris* forest, on and between post fire moss *Ceratodon purpureus* causing its dieback, 19th of November 2020, leg. P. Mohr, N. Scharnofski.

20230328-KF27 – Germany, east of Treuenbrietzen, Frohnsdorf, 12.914158 E, 52.037606 N, 95 m asl., *Populus*-succession on fire site (after two fires, 2018 & 2022)

on former *Pinus sylvestris* forest, on and between post fire mosses *Ceratodon purpureus* and *Funaria hygrometrica* causing their dieback, 28th of March 2023, leg. R. Jarling, J. Ehrlich.

Discussion

Arrhenia-species are either obligatory bryophiles, e.g., *A. retiruga* and *A. lobata*, others are lichenophiles, e.g., *A. peltigerina*, still others are not strictly moss-bound at all, such as species of the *acerosa*-complex (Voitk et al. 2020, 2022). Recently, Voitk et al. (2022) have shown that the species diversity of sphagnophilous *Arrhenia* is much greater than originally thought and that some are obligate and others facultative sphagnophiles, i.e., *A. bigelowii*, *A. gerardiana*, *A. telmatiaea*, and *A. philonotis*, respectively. *A. bryophthora* appears to be closely associated with *Ceratodon purpureus* and possibly *Funaria hygrometrica*, both dioicous mosses common on recent to old burnt areas. However, unlike the sphagnophilous and most other moss-dwelling *Arrhenia*, *A. bryophthora* causes a necrosis on its host and must therefore be considered a true parasite (Voitk et al. 2022). To our knowledge, a similarly destructive lifestyle is only known from the lichenophilic *A. peltigerina* (Diederich et al. 2022), which is macroscopically similar, but microscopically distinct by the presence of clamp connections and phylogenetically related to species of the *auriscalpium/spathulata* complex (Voitk et al. 2020).

Morphologically similar applies to *A. velutipes*, but this species has a faint odor of pelargonium, abundant clamp connections in all tissues and also differs in its molecular data (Bas et al. 1995; Vesterholt 2012). *Arrhenia obatra* and *Arrhenia obscura* can be macroscopically confused with *A. bryophthora*, as well, but both bare clamp connections (Bas et al. 1995; Vesterholt 2012).

Specimens of *Arrhenia bryophthora* were so abundant in late autumn, winter and early spring after the fire in all the areas studied (sometimes with hundreds of fruiting bodies on a few square meters) that it seems incredible to us that this species is not found in the literature (Moser 1983; Bas et al. 1995; Ludwig 2001; Vesterholt 2012). Ludwig (2001) mentioned in his comment on *Omphalina velutina* (= *Lichenomphalia velutina*) that it can occur after fires. Unfortunately, it is not clear where this information comes from. However, that species belongs to another lineage of omphalinoid agarics that are lichenized (Redhead et al. 2002b). Vesterholt (2012) remarks on *A. velutipes* that it can also occur on old fire places. It is noteworthy that these two species can have a distinct pubescent stipe, as we have seen in many young specimens of *A. bryophthora*. Therefore, we believe that confusion with *A. velutipes* or *L. velutina* may have occurred in the past.

In the phylogenetic tree based on ITS and LSU sequences (Fig. 1), all specimens of *A. bryophthora* group in the same moderately supported clade that is the most basal one of all sequences assigned to *Arrhenia* specimens. Considering the phylogenetic results presented in Fig. 1 and in the literature (Voitk et al. 2020, 2022; Zhang et al. 2022) and the fact that the current understanding of the genus *Arrhenia* includes species with facultative and obligate bryophilous, lichenophilous, and saprotrophic lifestyles as well as cyphelloid, pleurotoid, and omphalinoid habitus; it is plausible that this taxonomic group should be revised and studied in more detail in the future. This includes careful morphological and phylogenetic studies based on multi-locus sequencing and comprehensive sampling. Thus, we believe that *Arrhenia* s.l. will be split into further genera and consequently, *A. bryophthora* will be recombined into another, perhaps new, genus. However, in view of the critical discussions on the establishment of new genera (Vellinga et al. 2015), we consider it best not to establish a new monospecific genus for *A. bryophthora* at this point, but to include it in the current understanding of *Arrhenia* s.l.

Bryopistillaria clavarioides has been confused with *Clavaria tenuipes* Berk. & Broome in the past. That fact is caused by a description of *C. tenuipes* by Rea (1922), which was later accepted by Corner (1950). Rea was the first who included old charcoal heaps in the substrate range of *C. tenuipes*. This obviously wrong information was later adopted in keys to the genus *Clavaria*, even until recent times (Pilát 1958; Jülich 1984; Knudsen et al. 2012;). Schild (1981) described clavarioid specimens growing on recently burnt sites, but was convinced that these were related to another collection that came from a flowerpot in the garden of the Geobotanical Institute of ETH Zurich (Switzerland). Therefore, he concurred with Corner's opinion on *C. tenuipes* and grouped all these specimens under this taxon. Kajan (1986) and Kajan and Grauwinkel (1987) were the first to recognize that *C. tenuipes* Berk. & Broome and clavarioid specimens growing on recently burnt sites are not conspecific. They, however, incorrectly applied the taxon *C. tenuipes* to specimens growing exclusively on burnt sites (= *B. clavarioides*), and in turn established a new taxon, namely, *C. krieglsteineri*, for non-phoenicoid specimens.

Apart from the divergent ecology, the macroscopic description of *C. tenuipes* Berk. & Broome does not seem to correspond to *B. clavarioides*. Features like the pale clay-color and the up to 7 mm swollen head rather suggest a relation to *C. daulnoyae* Quel., or alike. In view of this and the fact that the type specimen is in poor condition (Schild 1981), we leave the clarification of what is to be understood as *C. tenuipes* to further studies.

All specimens of *B. clavarioides* discussed in this publication grew near or among the common fire mosses *Funaria hygrometrica* or *Ceratodon purpureus*. The same applies to

the specimens presented in Kajan and Grauwinkel (1987). According to these authors, *B. clavarioides* is not uncommon on burnt areas in the spring and autumn after a fire up to 2.5 years. At this point, it must be noted that although the clubs grew along and between *Funaria*, the moss always appeared healthy and fresh, without any necrosis (which neither we nor other authors have observed before). However, we could observe the dieback of *Ceratodon purpureus* growing in the vicinity of *B. clavarioides*. Whether this was actually caused by the *Bryopistillaria* is not clear to us.

Bryophily is common among members of the *Rickenellaceae*. *Muscinipta laevis* and *Bryopistillaria sagittiformis* grow biotrophically on mosses, but it is still controversial whether they also live facultatively saprotrophically (Olariaga et al. 2020). *Rickenella* spp., *Loreleia* spp., and *Blasiphalia pseudogrisella* (= *R. pseudogrisella*) and *Cantharelopsis prescottii* are strictly associated with various mosses and therefore cannot be found separately from their partner. Dentinger and McLaughlin (2006) who erected *Alloclavaria* as the first clavarioid taxon within the *Hymenochaetales*¹ suggested to test whether *A. purpurea* is bryophilic, because it is frequently found among mosses. However, later results suggested that it represents a new lineage of ectomycorrhizal fungi within the *Hymenochaetales* (Korotkin et al. 2018). The authors of the latter study also pointed out that *L. marchantiae* or *Blasiphalia pseudogrisella*, *Muscinipta laevis*, and *Rickenella swartzii* belong to the same ectomycorrhizal (ECM) cluster and can thus be classified as ECM or rather ECM-like. They specifically ruled out a parasitic lifestyle, but mentioned that a possible commensalism should not be dismissed unless the benefit to the fitness of their bryophytic partners will have been proven (Korotkin et al. 2018). Especially on our plots studied, we can exclude true ECM because most of the plant partners, i.e., *Pinus sylvestris* and *Betula pendula*, died in the fires, and other potential partners were missing. Therefore, a commensal (bryophilic) or even bryotrophic lifestyle of *B. clavarioides* is plausible.

Some representatives of the *Rickenellaceae* have hymenial cystidia or setae (*Rickenella/Alloclavaria* etc.); others do not (*Muscinipta laevis*, *B. sagittiformis*). Thus, it is not surprising that *B. clavarioides* has no cystidia, although it is assigned to the *Hymenochaetales*.

It is interesting that the spores of *B. clavarioides* often stick together in clusters (tetrads or more), which was also observed for *Bryopistillaria sagittiformis* (Olariaga et al. 2020) and *Rickenella* spp. (Ludwig 2001). Furthermore, it is remarkable that the latter author mentioned a high variability in spore size of *R. swartzii*, a fact that also applies to *B. clavarioides*.

¹ Note: later proposed by Vizzini (2010) to be placed in the *Rickenellaceae*.

Looking at the macro-morphology of *B. clavarioides* and *B. sagittiformis*, it is strange at first to place them in the same genus. While the club-shaped basidiocarps of *B. sagittiformis* are only up to 1.2 mm in size (Olariaga et al. 2020), *B. clavarioides* can form clubs that are up to 30 times larger. However, despite some little differences, their microscopic features match well; the spores are about of same size and lack an iodine reaction in both species (Olariaga et al. 2020). The RaxML-tree based on ITS and LSU loci (Fig. 2), the sequences of *B. clavarioides* and *B. sagittiformis* form a strongly supported clade. *B. sagittiformis* is biotrophic in/on various mosses and additionally can follow a saprotrophic lifestyle (Olariaga et al. 2020). The fact that *B. clavarioides* seems specific to its hosts, on the other hand, argues for a separate genus. Nevertheless, based on the available data, we do not consider it advisable to establish a new genus in this case and therefore follow the recommendation of Vellinga et al. (2015).

Finally, one question remains to be answered regarding the ecology of the two fungal species discussed here. Both are obviously associated with the mosses *Ceratodon purpureus* and/or *Funaria hygrometrica*. The mosses, for their part, prefer to grow on older burnt areas, but can also thrive outside former forest fire sites (fire-disturbed habitats). However, it has never been observed that the fungi were associated with the mosses when were no such sites. This phenomenon is remarkable and should be studied in more detail in the future.

Supplementary Information The online version contains supplementary material available at <https://doi.org/10.1007/s11557-024-01965-1>.

Acknowledgements We would like to thank Dr. Annika Busse, Dr. Torsten Bittner, and Stefan Müller for their support on site and permission to investigate the burnt areas in the Saxon Switzerland National Park and the Gohrischheide nature reserve. Furthermore, we thank the Stiftung Naturlandschaften Brandenburg and the Badenitzer Forstgemeinschaft for their permission to investigate the areas close to Jüterbog and Treuenbrietzen. Especially the volunteers, as mention above, are warmly thanked for their help with the field work and Madeleine Schäfer and Ian Volkmann for their lab assistance.

Author contribution All authors contributed to the study conception and design. Material preparation, data collection, and analysis were performed by Alexander Karich, René Ullrich, René Jarling, and Daniela Demski. The first draft of the manuscript was written by Alexander Karich, and all authors commented on previous versions of the manuscript. All authors read and approved the final manuscript.

Funding Open Access funding enabled and organized by Projekt DEAL. The work of R.J. and D.D. is funded by the Fachagentur Nachwachsende Rohstoffe (FNR, grant number: 2219WK50E4) within the framework of the PYROPHOB project.
